#### THE TRANSLATOR'S PREFACE.

Botany first presented themselves to me, in turning over the last complete edition of Rousseau's works, their elegance and simplicity pleased me enough to make me give them a second more attentive perusal. I then thought that they had considerable merit; and that if they were disembarrassed from the chaos of sisteen quarto volumes, and translated into English, they might be of use to such of my fair country women and unlearned countrymen as wished to amuse themselves with natural history.

When the translation was done, I perceived that, the foundation only being laid by the ingenious author, it could be of little fervice without raising the superstructure. This I have attempted; not flattering myself that it is executed in Rousseau's manner, which is inimitable, but merely with the design of being useful.

What books can you recommend, that may enable me to acquire a competent knowledge of Botany? is a question that has very fre-

<sup>&</sup>lt;sup>a</sup> Lettres Flementaires sur la Botanique à Madame de L\*. Melanges, tome ii. page 531, &c.

b Collection complete des Oeuvres de J. J. Rousseau, Geneve, 1782.

quently been asked me. To the learned I can readily answer-the works of Linnæus alone will furnish you with all the knowledge you have occasion for; or, if they are deficient in any point, will refer you to other authors, where you may have every fatisfaction that books can give you c. But I am not very folicitous to relieve these learned gentlemen from their embarrassment; they have resources enough, and know how to help themselves. As to the unlearned, if I were to fend them to the translation of Linnæus's works, they would only find themselves bewildered in an inextricable labyrinth of unintelligible terms, and would only reap difgust from a study, that is, perhaps, more capable of affording pleasure than any other. If I were to bid them fit down, and study their grammar d regularly; so dry and forbidding an outset might discourage the greater number; and few would enter the temple through a vestibule of forunpromifing an appearance. A language however must be acquired; but then it may

<sup>\*</sup> These writings of Linnæus are—Philosophia Botanica, that inexhaustible mine of elementary knowledge—Genera Plantarum—Species Plantarum—and Systema Vegetabilium, which is an epitome of the two last.

d In Lee's Introduction, Rose's Elements, &c.

be done gradually; and the tædium of it may, in some measure, be relieved by carrying on at the same time a study of sacts, and the philo-sophy of nature. This seems to have been Rousseau's idea, and I have endeavoured not to lose sight of it in my continuation of his eight ingenious letters.

Let an unlearned person then, who is defirous of acquiring fome knowledge of Botany, begin by taking a few plants with flowers, whose parts are sufficiently visible. and examine them patiently by the descriptions and characters which are given in the following pages: You may perhaps know fome plants by their names: or if not, you will be unfortunate indeed if you have not a friend who will show you the flower of a lily. If, in the course of your examination, any term should occur that is not explained in the page, of mentioned in the index, you may have recourse to the Dictionary, the Introduction, or the Elements. If you can have patience to go through the first seven letters, with a plant or two of each natural tribe explained in them; to make yourself master of the classification in the ninth and tenth: and to examine the obvious plants, whose characters are given in the twenty following

following letters, as they occur; I flatter my-felf that you will find little difficulty after that, in determining any plant which you shall happen to meet with, by Linnæus's characters, as delivered by his translators: whereas if you had begun with them, I am confident you would have been discouraged from proceeding.

Good plates, or figures of plants, will also be of considerable assistance: those of Mr. Curtis's Flora Londinensis will suffice for most of the British natives: especially as he has accompanied his plates with ample and accurate descriptions in English as well as Latin. Mr. Miller's figures to his Gardener's Dictionary, and Mr. Curtis's in his Botanical Magazine, exhibit a great number of the most remarkable foreigners. There is indeed no want of such helps: but the missortune is, that these books are so very expensive, as to be far beyond the purse of all but the opulent.

I beg

e A fystem of Vegetables, &c. translated from the 13th edition of Linnæus's Systema Vegetabilium, by a botanical society at Lichfield.——The Genera Plantarum is since also translated by the same hands.

f Catesby's Carolina. Martyn's Historia Plantarum Rariorum. Oeder's Flora Danica. Dillenius's Hortus Elthamensis. Besler's Hortus Eystettensis. Rheede's

I beg leave to protest against these letters being read in the easy chair at home; they can be of no use but to such as have a plant in their hand; nor do they pretend to any thing more, than to initiate such as, from their ignorance of the learned languages, are unable to profit by the works of the learned, in the first principles of vegetable nature. Botany is not to be learned in the closet: you must go forth into the garden or the fields, and there become familiar with Nature herfelf; with that beauty, order, regularity, and inexhaustible variety which is to be found in the structure of vegetables; and that wonderful fitness to its end, which we perceive in every work of creation, as far as our limited understandings, and partial observations, give us a just view of it.

In the second edition a few mistakes were corrected and some improvements were made;

Hortus Malabaricus. Rumphius's Herbarium Amboinense. Trew's Florum Imagines & Plantæ rariores. Jacquin's Flora Austriaca, Hortus Vindobonensis, &c. Ehret's Plantæ rariores. Hackwell's Herbal. Hill's Vegetable System. Merian's Surinam and European Plants and Insects. Allionii Flora Pedemontana. Pallas's Flora Rossica. Scopoli's Flora Insubrica. Dr. Smith's Icones Pictæ, &c.—are all very fine works, but it would cost an immense sum to purchase them.

the principal of these was, a reference at the foot of the page to some authors who have figured the plants. For this purpose I preferred Curtis and Miller: when these sailed me, I had recourse to the Flora Danica, &c. and I usually referred to old Gerard, or Morison, or both, for the sake of such as do not possess the more splendid works, and live remote from public libraries.

In the third edition these references were considerably multiplied; and that the plants which were wanted for examination might be the more readily found, the generic names were then first given in the margin, and a running title of the classes and orders was placed at the top of the page.

In the fourth edition some farther corrections and improvements were made; and the references to figures were, in a small degree, increased.

The fifth edition was printed from the fourth; but this has been carefully revifed throughout; and more references to figures given, particularly from those two elegant works, the Botanical Magazine and English Botany.

### CONTENTS.

INTRODUCTION. A fhort history of the rise and progess of Botany; particularly of Nomenclature and Systematic Arrangement.

LETTER I. The true use of Botany—the main thing to be learnt, not mere names, but the vegetable structure—component parts of a plant, p. 21—fructification explained—the parts that compose a flower—corolla, pistil, stamen, exemplified in the Lily, p. 2—the pericarp, p. 24—calyx, p. 25—character of the Liliaceous Tribe of plants, p. 25—Botany a study of observations and facts, p. 26.

LETTER II. Double flowers to be avoided in botanical examinations—analysis of the Stock-gilliflower, as an example of the tribe of Cruciform flowers, p. 28—divifion of the tribe into two orders, Siliquose and Siliculose, p. 31—small flowers to be examined with a glass—other instruments necessary for a botanist, p. 32.

LETTER III. Botany not to be studied by books, but by nature, p. 33—Analysis of the Pea slower, p. 34—distinc-

A 3 tion

tion of flowers into regular and irregular—precautions to bring the embryo to maturity, particularly in the pulse tribe, p. 35—Legume distinguished from the Silique, p. 8.—these all have flowers of the Peastructure, called Papilionaceous, p. 39.

LETTER IV. Reason why two stamens are shorter than the other four in Cruciform slowers, p. 40—glands at the base of the filaments—use of them, p. 41. Ringent slowers, p. 42—Labiate: Analysis of the white Dead-Nettle, p. 42—Personate—exemplified in Snap-dragon and Toad-slax, p. 45. Comparison of the Labiate and Personate flowers; with the true way of distinguishing them, p. 46.

LETTER V. Glands very small, p. 48—Botany not a science of words, but that which teaches the structure of Vegetables—The first thing to be learnt is how to see, and to exercise the understanding, p. 48. Disposition of the fructification in the umbellate tribe, p. 50—division of slowers into Inferior and Superior, p. 52—description of the flower and fruit of Umbellate plants, p. 52—proper character of the tribe, p. 53. Rule to avoid mistakes in ascertaining this character—instanced in the Elder, p. 54—in Eryngo; p. 55.—great similitude of umbellate plants—secondary characters to affist us in distinguishing them—Distinction of Fool's Parsley and Chervil, p. 57.

LETTER VI. The umbellate and other natural tribes of plants to be known by their habit, p. 60—corrected by an analysis of the fructification—Structure of Compound flowers exemplified in the Common Daify, p. 61—made up of stoscules or florets, p. 64—which are of

two forts, florets properly so called, and semi-florets, p. 64—these divide the whole tribe into three sections—

1. Semiflosculous flowers. 2. Flosculous. 3. Radiate. Distinction between Compound and Aggregate or Capitate flowers, p. 66—Receptacle the most effential part of a Compound flower—exemplified in the Dandelion, p. 67. The Calyx—double imbricate—Structure of a Floret, p. 68—and of a Semi-floret, p. 70—and of the change in the form of the calyx. Flowers most adapted for examination, p. 71.

nature changed and disfigured by us in many respects, p. 72—for the children of pure nature we must look in fields and woods. Fruit-trees, however, though ingrasted, retain their botanical characters. The different fruits are but varieties. Pear—Apple—Quince—Cherry—Plum—Apricot—Almond—Peach—Nedarine—their characters—and that of the class to which they all belong, p. 74.

LETTER VIII. The manner how to form an Hortus Siccus, or collection of dried plants. The use of it, to put us in mind of what we have once known, not to give us a knowledge of plants we have never seen before: which can only be had, by gathering them and examining them ourselves.

LETTER IX. The skill of a Botanist consists in finding out plants that are unknown to him——In order to this he must learn a system—which is artificial—but preferves the natural tribes hitherto explained. The Classes in the system of Linnæus explained, p. 85.

A 4

LETTER

LETTER X. Genera and species not to be determined without a regular arrangement, p. 98. The orders in the system of Linnæus explained.—Two tables of the characters of the Classes and Orders, p. 109.

LETTER XI. Explanation of generic and specific characters of plants begun—Monandriu—Hippuris, p. 115—Canna, p. 117.

LETTER XII. The examination of plants facilitated by the clearness and order of arrangement; and by proceeding regularly from generals to particulars, p. 119, The orders thrown into great subdivisions—instanced in the first order of the second class, p. 120—Diandria—J smine, p. 121—Privet, Phillyrea, Olive, Lilac, Veronica, p. 122—Butterwort—Vervain—Rosemary—Sage, p. 124.

LETTER XIII. Corn and Grasses—the most useful and pleasant tribe of plants, p. 127—more than 300 species of Grass—the flowers have all the constituent parts, p. 128.—Mostly belong to the second order of the third class, p. 129. General character of the whole tribe—its four subdivisions, p. 132——Canary grass, Foxtail, Cat's-tail, p. 133—varieties from soil and situation, p. 134. Melica, Aira, p. 135.—Briza, Poa, Festuca, Brome, Oats and Oat-grass, Reed, p. 135, &c.—Rie, Wheat, Barley, Darnel, Dog's-tail, p. 143—Vernal, p. 150—Cinna—Soft, p. 151—Bog-rush, Cyperus, Club-rush, Cotton-grass—Cat's-tail, Bur reed, Sedge, Rush, Sugar, p. 153.

LETTER XIV. Other plants of the third class-Iris.

LETTER XV. The fourth class—Aggregate flowers— Teafel, Scabious, p. 159. Stellated Plants—General habit habit a leading circumstance, but not to be finally depended upon, p. 163—Madder, Sherardia, Woodroof, Galium, p. 164. Plantain, p. 165—By a careful examination of known plants, a facility acquired in detecting such as are unknown, p. 166—Common plants preferred to rare ones, p. 167—and why—Ladies-mantle, p. 167—Dodder, p. 168—Pondweed, p. 169.

LETTER XVI. The fifth class, Pentandria, and the first order Monogynia. The natural order of Preciæ, p. 171 Primrose, Ox-lip, Cowslip, Polyanthus, p. 172-General directions for the examination of plants, p. 173 -Dodecatheon or Meadia, Cyclamen, p. 175-Marsh Trefoil, p. 176-Water Violet, p. 177-Another natural order of Asperifoliæ or Rough-leaved, p. 177-Turnfole, p. 179-Mouse-ear Scorpion-grass, Gromwell, p. 180-Hound's-tongue, Comfrey, p. 181-Cerinthe, Borage, Bugloss, p. 182-Viper's Bugloss. Campanaceæ or Bell-flowers-Convolvulus or Bindweed. p. 183-Ipomæa, Campanula, p. 185-Polemonium, p. 189. Caution not to be missed by vulgar names, Natural order of Luridæ, p. 190-Verbascum, or Mullein, p. 191-Datura or Thorn-Apple, p. 192-Henbane, p. 103-Tobacco, p. 194-Deadly Nightshade, p. 195-Mandrake, p. 197-Winter Cherry, p. 198-Nightshade, p. 199-Potato, p. 201-Egg-plant, Capsicum, p. 202. Shrubs-Honeysuckle, p. 204-Buckthorn, Berry bearing or Black Alder, p. 206-Alaternus, Christ's-thorn, p. 207 - Coffee, p. 208-Cestrum, Diosma, p. 209 Specious plants-Lychnidea Marvel of Peru, p. 210-Crested Amaranth for Cock'scomb, p. 211. Natural Order of Contortæ, p. 212-Periwincle, p. 213-Oleander, p. 214-Cape Jasmine, Plumeria,

meria, p. 215—Jesuit's-bark—Asclepias, p. 216—Stapelia, p. 217. Institut control of the policy of the

LETTER XVII. Nectary what-its use-and the variriety of its forms, p. 220. The fecond Order of the fifth class-Oleraceous plants-Goosefoot, Beet, p. 221 -Glaffwort, p. 222-Globe Amaranth, p. 223-Elm, Gentian, p. 224. Leffer Centaury, Yellow Centaury, p. 226—The Umbellate tribe—Hemlock Chervil how to distinguish it from Garden Chervil, p. 227-Water Parsnep, how to distinguish it from Water Cresfes, p. 229-Hemlock, p. 230-Wild Chervil, or Cowweed, Rough Chervil, p. 231-Umbellate plants used for food, Carrot, p. 232-Sampire, p. 233-Angelica, p. 234-Coriander, Parsnep, Fennel, p. 235-Carraway, Parfley, Smallage, Celeri, p. 236-Earth-nut, or Pignut, Ferula, Cow-Parsnep, p. 237-Shepherd's-needle. The third Order-Sumach, p. 238-Wayfaring-tree, · Marsh-Elder, Gelder Rose, Laurustinus. The fourth Order-Parnassia, p. 239. The fifth Order-Thrift, Flax. p. 240.

LETTER XVIII. Hexandria Monogynia—Liliaceous plants, p. 242—all of them not in this Class—some other genera mixed with them—divided into three sections from the calyx. I. Ananas, p. 243—Tradescantia. 2. Snowdrop, p. 244—Narcissus, p. 245—Amaryllis, p. 246. 3. Tulip, p. 248—Lily of the Valley, Hyacinth, p. 249—Aloe, p. 250—Plants not liliaceous—Barberry, Calamus aromaticus, p. 251—Rattan, Rush. Second Order, Digynia—Rice. Third Order, Trigynia—Dock, p. 252—Meadow Saffron. Fourth Order, Water Plantain, p. 254.

LETTER XIX. Heptandria, the smallest of all the Classes - Horse Chesnut, p. 255. Octandria, the eighth Class -Indian Crefs, Tree Primrofe, p. 256. Willow Herb, Heath, p. 257-Mezereon-Spurge Laurel, p. 259. Second Order, Yellow perfoliate Gentian. Third Order, Biffort, p. 260. Knot-grass, Buckwheat, Black Bindweed, p. 261. Enneandria, the ninth Class, a very fmall one, p. 261.-Bay, Acajou or Cashew, p. 263.—Rhubarb, p. 263—Flowering Rush, p. 266. Decandria, the tenth Class. The first Order-Dittany or Fraxinella, p. 267 - Dionæa Muscipula, Rue, p. 267. 268-Arbutus or Strawberry-tree. Second Order-Saxifrage, p. 269-Dianthus, Sweet William, Carnation, Pink, China Pink, p. 272-Third Order-Arenaria. Stellaria, Cucubalus, Silene, p. 273. Spratling Poppy. Fourth Order-Sedums or Stone-crops, p. 274-Cockle, Lychnis, p. 275.

LETTER XX. The eleventh Class, Dodecandria—
Number of stamens from 12 to 19—First Order, p. 277
—Asarabacca, Purslain, Loosestrife, p. 278. Second Order—Agrimony, p. 279. Third Order—Dyer's-weed or Weld, Sweet Reseda, p. 280—Euphorbia or Spurge, p. 281. Last Order—House-leek, p. 284.

LETTER XXI. Class Icofandria—confists much of trees and shrubs, especially Fruit-trees——Rule to distinguish it, p. 286—Cactus, Melon-thistle, Torch-thistle, Indianfig, p. 287—Syringa, Myrtle, p. 280. Second Order—Cratægus, p. 290. Third Order—Mountain Ash, Service. Fourth Order—Apple, Pear, Quince, Medlar, Spiræa, p. 291—Ficoides or Fig-marigold, p. 292. Last Order—Rose, p. 293—Strawberry, p. 294. Class Polyandria—Reasons why it is kept distinct from the for-

mer, p. 294—Poppy, p. 295—Caper, Tea-tree, Lime, Water-lily, Ciftus, p. 296, 297. Multifiliquous plants—Peony, Larkspur, Aconite, Columbine, Hellebore, p. 297, 298—I ulip-tree, p. 299—Magnolia, p. 300—Hepatica, Pasque slower, Wood Anemone, Eastern and Garden Anemonics, p. 301—Ranunculus, p. 302.

Letter XXII. Fourteenth Class, Didynamia. Classical character, p. 305. First Order—Gymnospermia, Verticillate plants—Ground Ivy, Mint, Lavender, p. 306—Teucrium Bugle, Betony, Cat-mint, p. 307—Black Horehound, White Horehound, Wild Thyme, p. 308—Garden Thyme, Basil, Marjoram, p. 309—Dittany of Crete, Baum, Baum of Gilead, p. 310—Self-heal, Scutellaria p. 311. Second Order—Angiospermia, Broomrape, Rinanthus, or Yellow rattle, p. 312—Eve-bright, Toad-slax, p. 313—remarkable change in this plant—Snap-dragon, p. 314—Three-leaved Toad-slax. Figwort, p. 315—Foxglove, Trumpet-slower, p. 316—Catalpa, Acanthus, p. 317—Plants named from eminent perfons, p. 318.

LETTER XXIII. Fifteenth Class—Tetradynamia. Classical character, p. 319. First Order—Siliculose—Honesty or White Satin, p. 320—Candy-tust, Scurvy-grass, Horse-radith, p. 321. Second Order—Siliquose—Radith, Erysimum, p. 322—Winter-cress, Sauce-alone, Stock, Wall-slower, Rocket, p. 323—Arabis, Cabbage, Turnep, Coleseed, Woad, Sea Colewort, p. 324—Cardamine, Mustard, Charlock, p. 325—Water-cress, p. 326—Flixweed, p. 327.

LETTER XXIV. Plants to be examined at different feafons. Class Monadelphia, p. 328. Classical character. Five Orders—their character—and that of the genera, p. 329—Hermannia, p. 331—Geranium, p. 332—Marsh-Mallow; Mallow, p. 341—Hollyhock, p. 342—Althæa Frutex, p. 343—China Rose, Musk, p. 344.

LETTER XXV. Class seventeenth-Diadelphia. Orders four from the number of stamens, p. 345-Fumitory -Milkwort, p. 346. Order Decandria, Papilionaceous flowers, p. 347-Character of the Order, p. 349-Spanish Broom, p. 350-Common Broom, White Spanish Broom, Portugal Broom, Prickly Cytisus, p. 351-Dyer's Weed, Needle Furze, Common Furze, Restharrow, p. 352-Ladies' finger, Jupiter's beard, p 353-Lupin, p. 354-Kidney Bean, Everlasting Pea, p. 356-Yellow Vetchling, Crimfon Grass Vetch, Sweet-scented Pea, Painted Lady Pea, Tangier Pea. p. 357-Vetch or Tare, p. 358-Bean, Bladder Sena, p. 360-Scarlet Colutea, Herbaceous Colutea, p. 361-Laburnum, Cytisus, p. 362-Bastard Acacia, Caragana, p. 363-Scorpion Sena, Indigo, p. 364-Liquorice, p. 365-French Honeysuckle, Saintfoin, Trefoil, p. 366-Lotus, Lucerne, p. 367-Heart-clover, Snails, Hedge-hogs. p. 368-Caterpillars. Class Polyadelphia, p. 369-Citron, Orange, Lemon, Shaddock, p. 370-St. John's Wort, p. 372-St. Peter's Wort, p. 373-Tutsan, Majorca St. John's. Wort, p. 374-Chinese Hypericum. P. 375.

LETTER XXVI. Class Syngenesia or Compound Flowers, p. 376. First Order—Polygamia Æqualis, p. 377—Goat's-beard. How to distinguish a Double from a Compound Flower, p. 378.—Salfafy, Scorzonera, p. 379—Sowthistle, Lettuce. Way to distinguish plants of the

fame natural Class, p. 385-Hawkweed, Succory, Endive. p. 381-Thiftles, Wav-thiftle, p. 382-Cotton thiftle, Artichoke, Burdock p. 383-Eupatorium, Bidens, p. 384. Second Order-Polygamia Superflua. Tanfy, p. 385-Southernwood, Common Wormwood, Roman Wormwood, p. 3 6.-Mugwort, Sea Wormwood, Yellow and White Everlasting, p. 387-Xeranthemum, Colt'sfoot, p. 388-Butter-bur, Groundsel, p. 389-Ragwort, African Groundsel, p. 390-Aster, Golden-rod, p. 301-Elecampane, Flea-bane, p. 303-Leopard'sbane; p. 304-French and African Marigolds, p. 305-Ox-eye Daify, Corn Marigold, p. 306-Chryfanthemum, Feverfew, Camomile, Milfoil, p. 398. Third Order-Polygamia Frustranea, p. 398-Annual Sunflower, Perennial Sunflower, p. 399 - Jerusalem Artichoke, p 400-Sweet Sultan, Great Centaury, Common Knapweed, p 401-Great Knapweed, Blue-bottle, Mountain Blue-bottle, Carduus benedictus, p. 402-Star thiftle. Fourth Order-Polygamia Necessaria, Marigold, p. .403. Fifth Order-Polygamia Segregata, Globe-thiftle. Sixth Order-Monogamia, p. 404. Sweet Violet, Dog Violet, Pansies, p. 405-Balfamine, Wild Balfam, p. 406, 407.

LETTER XXVII. The twentieth Class—Gynandria.

Character. First Order—Diandria. A Natural tribe, p. 409 Its character, p. 410—Leading characters of the principal genera—Orchis, Buttersly, p. 412—Pyramidal, p. 413—Male, Female, p. 414—Dwarf, p. 415—Broad-leaved, Spotted, p. 416—Sweet Satyrium—Lizard, Frog, p. 417—Ophrys—Twaythade, Spiral, p. 419—Fly, Bee, Spider, p. 420—Lady's Slipper, p. 422.

p. 422. Order Pentandria—Passion flower, p. 423. Order Polyandria—Arum, p. 427.

LETTER XXVIII. The twenty-first Class-Monæcia. Character, p. 429-Order Triandria contains a natural tribe called Calamariæ. Cat's-tail, p. 430-Bur-reed. p. 431—Mays, p. 432—Sedge, p. 433. Trees in Order Tetrandria, p. 433-Birch, Alder, p. 434-Box, Mulberry, p. 435. In Order Polyandria: Oak, p. 436-Ilex, p. 437-Cork, Walnut, p. 438-Chefnut, Beech. p. 439-Hornbeam, Hazel, p. 441-Plane, p. 442. In Order Monodelphia: Pines, p. 443—Cedar, Larch, Firs. p. 445-Cypress, p. 446. Herbs in Order Tetrandria: Nettles. In Order Pentandria: Amaranth, p. 447. Order Polyandria: Arrow head, Burnet, p. 449. Order Monodelphia: Palma Christi. In Order Syngenesia: the natural tribe of Cucurbitaceæ, p. 450-Spirting Cucumber, Gourd, Pompion, Squash, p. 451-Me-Ion, Cucumber, p. 452.

LETTER XXIX. The twenty-fecond Class—Diæcia. Character. Order Diandria: Willow, p. 453. Order Tetrandria: Misseltoe, p. 455. Order Pentandria: Spinach, Hemp, Hop, p. 456. Order Hexandria: Black Bryony. Order Octandria: Poplars, p. 457. Order Enneandria. Dog's Mercury, p. 458. Order Monadelphia: Juniper, Savin, American Cedars, p. 459—Yew, p. 460. Order Syngenesia: Ruscus, Alexandrian Laurel, p. 461.

LETTER XXX. The twenty-third Class—Polygamia. Character. Order Monœcia: Valantia, p. 463—Pellitory, p. 464—Attiplex, Maple, p. 465—Sensitive, p. 466.

### INTRODUCTION.

THE principal misfortune of Botany is, that from its very birth it has been looked upon merely as a part of medicine. This was the reason why every body was employed in finding or supposing virtues in plants, whilst the knowledge of plants themfelves was totally neglected: for how could the same man make such long and repeated excursions as so extensive a study demands; and at the same time apply himself to the sedentary labours of the laboratory, and attendance upon the fick; which are the only methods of ascertaining the nature of vegetable substances, and their effects upon the human body? This false idea of Botany, for a long time, almost confined the study of it to medicinal plants, and reduced the vegetable chain to a small number of interrupted links. Even these were very ill studied, because the substance only was attended to, and not the organization. How indeed could persons be much interested in the organical structure of a substance, of which they had no other idea but as a thing

to be pounded in a mortar! Plants were fearched for, only to find remedies; it was fimples, not vegetables, that they looked after. This was very right, it will be faid. May be fo. Hence nevertheless it follows, that, if men were ever so well acquainted with remedies, they were very ignorant of plants; and this is all that I have here advanced.

Botany was nothing; there was no fuch study; and they who plumed themselves most upon their knowledge of vegetables, had no idea of their structure, or of the vegetable œconomy. Every body knew by fight five or fix plants in his neighbourhood, to which he gave names at random; enriched with wonderful virtues, which he took it in his head they possessed; and each of these plants, changed into an universal panacea. was alone sufficient to render all mankind immortal. These plants transformed into balfams and ointments, quickly difappeared; and foon made room for others, to which new comers, in order to distinguish themselves, attributed the same effects. Sometimes it was a new plant, decorated with ancient virtues: fometimes old plants, under new names, fufficed to enrich new quacks. These plants had a different vulgar name in every province, and they who pointed them out for their drugs, at most gave them only those names by which they were known on the spot where they lived: thus,

thus, when their recipes travelled into other countries, it was no longer known what plant they spoke of; every body substituted another after his own fancy, without regarding any thing else but giving it the same name. Such is the whole art that the Myrepsuses, the Hildegardises, the Suarduses, the Villanovas, and the rest of the doctors of that time, employed in the study of those plants which they treat of; and it would be difficult perhaps for any body to know one of them by the names or descriptions which they have given them.

At the revival of learning, every thing disappeared to make room for the works of antiquity; nothing was then either good or true but what was to be found in Aristotle or Galen. Instead of searching for plants where they grew, men studied them only in Pliny and Dioscorides; and there is nothing so frequent in the authors of those

Myrepsus's book is entitled Antidotarium parvum. Hildegardis was a lady and an abbes; she flourished about 1180, and wrote, among others, a treatise entitled Physica, Leguminum, Fruciuum, Herbarum, &c. Suardus's book is entitled Antidotarium, and was printed at Venice 1551, fol.—Arnoldus de Villanova put together Regimen Sanitatis Salerni, printed in 1482, 1484, 1490, 1491, 1493, 1505, 1509, &c. and was author of many other medical and medico-botanical works. He is said to have died in 1313. But the most popular of these old works, was Hortus Sanitatis, ascribed to Cuba. See Pulteney's Sketches of the Progress of Botany in England, chap. iv.

times, as to find them denying the existence of a plant, for no other reason but because Dioscorides has not mentioned it. These learned plants however must be found in nature, in order to make use of them according to the precepts of their master. They bestirred themselves therefore, they fet themselves to fearch, to obferve, to conjecture, and made every effort to find, in the plant which they chose, the characters described in their author: and fince translators, commentators, and practitioners seldom agreed in their choice, twenty names were given to the same plant; and the same name to twenty plants; every man maintaining that his own was the true one, and that all the rest, not being that of Dioscorides, ought to be proscribed. From this conflict indeed it followed at length that more careful refearches were made, and some good observations, which deserved not to be forgotten; but at the same time such a chaos of nomenclature, that the Physicians and Herbarists no longer understood each other: there was no pof-fibility of communicating their mutual lights; nothing remained but disputes upon words and names; and even every useful enquiry and description was lost, for want of being able to decide what plant each author had spoken of.

Real botanists however began to be formed: such as Clusius, Cordus, Cæsalpinus,

Gesner;

Gesnerb; good and instructive books on this subject began to be published, in which already appeared some traces of methods. And it has certainly been a loss that these pieces have become useless and unintelligible by the mere discordance of names. But these authors, beginning to unite species and separate genera, according to their own manner of observing the habit and apparent structure, occasioned new inconveniencies, and a fresh obscurity; because each author, regulating his nomenclature by his own method, created new genera,

hould have been Cordus 1515, Gefner 1516, Czefalpinus 1519, Clufius 1506: if we range them from the dates of their publications, they should stand thus—Cordus 1535, Gefner 140, Clufius 1557, Czefal-

pinus. 1583.

c Indeed!—Some traces only of method in the celebrated work of Cæsalpinus! He who first invented a complete arrangement of plants, and stands unrivalled as the father of method! He to whom every succeeding system-monger owes so many obligations! Though among them all Ray alone confesses it. What Rousseau affirms is true only of the excellent, the illustrious Gesner; the other two thought nothing of arrangement: No, nor the Bauhins, nor any other, till Morison and Ray.

d If Rousseau means to speak here concerning the works of the forementioned authors, this is not true. The treatises of Gesner and Clusius are every where referred to, even by Linnæus, and consequently their nomenclature is well known. The principal work of Valerius Cordus is Gesner's History of Plants, which he published in 1561. Cæsalpinus's book is now become rather a matter of respectable curiosity than use.

or feparated old ones, as the characters of his own required. So that genera and species were so jumbled together as to leave scarcely any plant without as many names as there were authors who described it; which made the study of the nomenclature as tedious as that of the plants themfelves, and frequently more difficult.

At length the two illustrious brothers appeared; who alone have done more for the advancement of Botany than all the rest together who preceded, and even followed them, till Tournesort. Rare geniuses! whose vast knowledge and solid labours, consecrated to Botany, render them worthy of that immortality which they have acquired. For till this part of natural history salls into oblivion, the names of John and Caspar Bauhin will live along with it in the memory of mankind.

Each of these men undertook an universal history of plants: but what more immediately relates to our present purpose is, that they each of them undertook to join to it a Synonymy, or exact list of the names that every plant bore in all the writers which preceded them. This labour was become absolutely necessary to enable us to reap any advantage from their obser-

e John the elder was born at Lyon in 1541, and died in 1613. Caspar was not born till 1560, and died in 1624.

vations; for without that, it was almost impossible to follow and distinguish every

plant among fo many names.

The eldest almost completed this undertaking in three volumes in folio, printed after his death; and he has given such just descriptions of the plants, that we are

rarely deceived in his fynonymsf.

The brother's plan was yet more extenfive, as appears by the first volume which he published, and from which we may judge of the immensity of the whole work, if he had found time to execute it !: but, excepting this volume, we have no more than the titles of the rest in his Pinaxh; and this Pinax, the produce of forty years labour, is still the guide to all those who study

Chabraus was the editor, and Francis Louis de Graffenried, of Bern, was at the expence of the publication. This work derives no excellence from the paper or print. The plates are fmall and poorly executed; they belonged to Fuchfius, and were purchased by the bookseller for this purpose; the editor has not unfrequently put them in wrong places. John Bauhin's History however has great intrinsic excellence, for the number of plants well described, and a judicious compilation of whatever had been done before his time. It is entitled " Historia Plantarum Universalis, auctore Johanne Bauhino archiatro, &c. Ebrod. 1651."

g Theatri Botanici pars I. Basil 1658 and 1663,

h Pinax Theatri Botanici, five Index in Theophrasti, Dioscoridis, Plinii & Botanicorum, qui a seculo scripferunt, opera, plantarum circiter 6000 nomina cum fynonymiis & differentiis. Opus XL annorum. 1623 & 1671, 4to. B 4

this fubject and wish to consult ancient authors.

The nomenclature of the Bauhins being formed only from the titles of their chapters, and these titles usually comprising several words, hence came the custom of giving, as the names of plants, long ambiguous phrases; which made this nomenclature not only tedious and embarraffing, but pedantic and ridiculous. I own there might have been some advantage in this, provided their phrases had been better constructed; but being composed indifferently of the names of places whence the plants came, of persons who sent them, and even of other plants to which they fancied them to bear some similitude, these phrases were fources of new embarrassment and fresh

Haller says also of this par nobile fratrum, that for their unwearied diligence they well deserved to lead the way in a new age of Botany; and accordingly he puts them at the head of the Collectores in his fixth book.

doubts,

i The judicious, the indefatigable Haller, from whose judgment there lies no appeal, says of Caspar Bauhin, that he emulated his elder brother in Botany; that he was laborious in collecting, and knew a greater number of plants, being more enriched with them by his scholars and friends: but that his judgment was less acute; that he admitted too many varieties for species; that he has repeated the same plant under different names; that he was less accurate than his brother in his descriptions, less acquainted with the natural classes, and unfortunate as well as himself in being obliged to divide his time between Anatomy and Botany. Bibl. Botan. I. p. 384.

doubts, because the knowledge of one plant required that of several others to which the phrase referred, and whose names were not better determined than its own.

In the mean time distant voyages were incessantly enriching Botany with new treasures; and, whilst the old names already overloaded the memory, it was neceffary to invent new ones for the new plants that were discovered. Lost in this immense labyrinth, the botanists were obliged to feek a thread to extricate themfelves from it; they attached themselves therefore at last seriously to method: Herman, Rivinus, Rayk, feverally proposed their own; but the immortal Tournefort carried away the prize from them all1; he first ranged the whole vegetable kingdom fystematically"; and reforming the nomenclature in part, combined by his new

<sup>1</sup> Tournefort first published his System in 1697: it was specious, and generally fashionable, till Linnæus's superfeded it: the plates of generic characters are excellent.

The order should have been Ray, Herman, Rivinus. Ray published his first work in 1660, his Method in 1682, and even drew up Tables for Bishop Wilkins in 1667, which were printed in the year following. Herman began to write in 1687, and printed his Method in 1690. Rivinus published the first part of his Method in 1690. Morison had before published his in 1669.

m How far this is true may be seen in note (k). Tournefort's, however, may be said to have been the first complete regular arrangement; though how it could ever be used to good purpose, without any characters or descriptions of the species, I do not understand.

genera with that of Caspar Bauhin: but, far from freeing it of its long phrases, he either added new ones, or loaded the old ones with additions which his method obliged him to make. The barbarous cuftom was then introduced of tagging new names to the old ones by a contradictory qui quæ quod, making of the same plant two distinct genera.

For instance—' Dens Leonis qui Pilo-6 fella folio minus villoso. Doria quæ Ja-

' cobcea orientalis limonii folio. Titano-

keratophyton quod Lythophyton mari-

Thus was the nomenclature loaded. The names of the plants became not only phrases but periods. I shall cite one of Plukenet's, to prove that I do not exaggerate. "Gramen myloicophorum caro-" linianum, feu gramen altissimum, pani-" cula maxima speciosa, e spicis majoribus " compressiusculis utrinque pinnatis blat-" tam molendariam quodam modo referen-" tibus, composita, foliis convolutis mu-" cronatis pungentibus." Almag. 137".

It would have been all over with Botany if this practice had continued; the nomenclature, being now absolutely insupportable, could no longer subfift in this flate; and it was become necessary either that a reformation should be made, or that

<sup>&</sup>lt;sup>n</sup> See Linnæus's Critica, and Philosophia Botanica.

the richest, the most lovely, and the easiest of the three parts of Natural History should be abandoned.

At length Linnæus, full of his system and the vast ideas which it suggested to him, formed the project of new moulding the whole; a talk which every body felt the necessity of, but no one dared to undertake. He did more, he executed it: and, having prepared in his Critica Botanica the rules by which it ought to be conducted, he determined the genera of plants in his Genera Plantarum, and afterwards the species in his Species Plantarum'; in fuch a manner, that, by keeping all the old names that agreed with these new rules, and new casting all the rest, he established at length a clear nomenclature, founded upon the true principles of the art which he had fet forth. He preserved all the ancient genera which were truly natural; he corrected, fimplified, united, or divided the

o The first sketch of Linnæus's System was published in 1735: the last edition of Systema Vegetabilium in 1784: the Critica Botanica in 1757: the first edition of the Genera the same year, and the last in 1764: the first edition of the Species in 1753, the second in 1762 and 1763. See Dr. Pulteney's excellent account of the writings of Linnæus. Improved editions of these celebrated works have been published since the death of Linnæus: as of Systema Vegetabilium by Murray and Persoon; of Genera Plantarum by Reichard and Schreber; and of Species Plantarum by Reichard and Willdenow. These last indeed comprehend Systema Vegetabilium also.

rest as their true characters required. And in forming his names he followed, sometimes even somewhat too severely, the rules which he had laid down.

With respect to the species, descriptions and distinctions were necessary to determine them; phraies therefore remained always indispensable; but, by confining himself to a fmall number of technical words, well chosen and well adapted, he made good Thort definitions deduced from the true character of the plant, banishing rigorously all that was foreign to it. For this it was neceffary to create a new language for Botany, that would spare the long periphrases of the old descriptions. Complaint has been made that the words of this language are not all to be found in Cicero. This complaint would be reasonable, had Cicero written a complete treatife of Botany. Those words however are all either Greek or Latin, expressive, short, sonorous, and even form elegant constructions by their extreme precision. It is in the constant practice of the art, that we feel all the advantage of this new language, which is as convenient and necessary for Botanists, as that of algebra is for mathematicians.

Hitherto Linnæus had indeed determined the greatest part of known plants, but he had not named them; for defining a thing is not naming it: a phrase can never be a true name, nor can it come into

common

common use. He provided against this defect by the invention of trivial names, which he joined to the generical ones in order to distinguish the species. By this contrivance the name of every plant is composed only of two words, which alone, when chosen with discernment, and applied with propriety, often make the plant better known than the long phrases of Micheli and Plukenet. To be still better and more regularly acquainted with it, there is the phrase, which doubtless must be known, but need not be repeated every time we have occasion to speak of the object.

Nothing is more pedantic or ridiculous, when a woman, or one of those men who resemble women, are asking you the name of an herb or a slower in a garden, than to be under the necessity of answering by a long sile of Latin words that have the appearance of a magical incantation; an inconvenience sufficient to deter such frivolous persons from a charming study offered with so pedantic an apparatus.

However necessary or advantageous this reform might be, nothing less was wanting than Linnæus's profound knowledge to execute it with success, and the reputation of this great naturalist to make it be uni-

P These specific or trivial names appear first in the Pan Suecicus of 1749; but they were brought to perfection in the first edition of the Species Plantarum, published four years after.

verfally adopted. It met with refistance at first, and meets with it still. This could not be otherwise; his rivals in the same career look upon this adoption as a confession of inferiority which they do not like to make; his nomenclature seemed so much of a piece with his system, that they could not well be separated. And Botanists of the higher order, who think themselves obliged through pride not to adopt the system of any other, but each man to have his own, will not sacrifice their pretensions to the progress of an art for which the professors have rarely a disinterested fondness.

National jealousies also oppose the admission of a foreign system. People think themselves obliged to support the samous men of their own country, especially after their death; for even that self-love which made them scarcely bear their superiority whilst they were alive, is honoured by their

glory after they are departed.

The great convenience however of this new nomenclature, and the utility of it, which practice has made known, have caused it to be adopted almost universally throughout Europe, sooner or later; and even at Paris M, de Jussieu has established it in the royal garden; thus preferring public utility to the glory of new-moulding the whole, which the method of natural samilies, invented by his illustrious uncle, seemed to require.

require. Not that the nomenclature of Linnæus is without its faults, or gives no handle to criticism; but, till a more perfect one shall be found, in which nothing is wanting, it is far better to adopt this than to have none, or to fall again into the phrases of Tournefort or Caspar Bauhin. I can even scarcely believe that a better nomenclature will in future have fuccess enough to profcribe this, to which the Botanists of Europe are at present so wholly accustomed; and, having now the double tie of habit and convenience, they will renounce it with still more unwillingness than they found in adopting it. In order to bring about fuch a change, an author must be found with credit enough to efface that of Linnæus; one to whose authority all Europe would be willing a fecond time to fubmit; which appears to me not likely to happen. For if his fystem, however excellent it may be, should be adopted by one nation only, it would throw Botany into a new labyrinth, and do it more injury than service.

Even the labour of Linnæus, though im-

<sup>&</sup>lt;sup>q</sup> The French garden however is certainly arranged by M. de Justieu's natural method; which was published in 1789, under the title of Genera Plantarum, secundum ordines naturales disposita, juxta methodum in horto regio Parisiensi exaratam, anno 1774.

The should rather have said nomenclature or language. It is of no great importance what system we adopt, so that we all agree to talk the same language. That of Linnæus will probably stand the test of ages, whatever may become of the sexual system.

mense, remains still impersect, inasmuch as it does not comprehend all known plants, and is not adopted by all Botanists without exception; for the writings of such as do not submit to it, require from their readers the same labour to settle the synonyms, as they were forced to take for those which

preceded it.

We are obliged to Mr. Crantz, notwithstanding his rage against Linnæus, for having adopted his nomenclature, though he rejected his system. But Haller, in his large and excellent work on the Swiss plants, rejects both; and Adanson does more; for he makes an entire new nomenclature, and furnishes no information whereby we may refer it to Linnæus's. Haller always quotes the genus, and frequently the specific characters of Linnæus; but Adanson never quotes either. Haller attaches himself to an exact fynonymy, by which, even when he does not add Linnæus's enunciation of the species, we may find it at least indirectly by the relation of the fynonyms. But Linnæus and his books are absolutely null and void for M. Adanfon and his readers, because the latter gives no information whereby we may connect them. So that we are compelled to choose between Linnæus and M. Adanson.

Alberti v. Haller Historia Stirpium Indigenarum Helvetiæ inchoata. Bernæ 1768 folio, in three volumes.

who excludes him without mercy; and to throw all the works of one of them into the fire. Or else we must undertake a new work, which will be neither short nor easy, to connect these nomenclatures, which of-

fer us no point of union.

Linnæus indeed has not given a complete fynonymy. For plants known long fince, he has contented himfelf with quoting the Bauhins and Clutius, with a figure of each plant. For exotic plants lately difcovered, he has cited one or two modern authors and the figures of Rheed, Rumphius, and fome others, and has gone no farther. His undertaking did not require of him a more extended compilation, and it is sufficient that he has given one certain information with regard to every plant which he names!

Such is the prefent state of things. Now after this account of it, I would ask every reader of common sense, how it is possible to attach one's self to the study of plants, and at the same time to reject that of the nomenclature? It is just as if a man would make himself skilful in a language, with a determination not to learn the words of it. The names, it is true, are arbitrary, the knowledge of plants has no necessary connexion with the nomencla-

<sup>\*</sup>Rouffeau means to speak here of the Species Plantarum, and what he says is in general true of that. But in his Flora Lapponica, Succica, &c. he has given a much more extensive synonymy.

ture; and it is easy to conceive that an intelligent man might be an excellent Botanist, without knowing a fingle plant by its name. But that one man alone, without books or any affiftance from communicated information, should become of himself even a very moderate Botanist, is a ridiculous affertion to make, and an enterprise impos-fible to execute. The question is, whether three hundred years of study and observation should be lost to Botany; whether three hundred volumes of figures and defcriptions should be thrown into the fire; whether the knowledge acquired by all the learned who have confecrated their purse, their life, their time, to distant, expensive, painful, and dangerous expeditions, should be useless to their successors; and whether every one fetting out from nothing could arrive by himfelf at the fame knowledge that a long feries of enquiry and study has spread over the mass of mankind? If not, and if the most lovely part of natural history merit the attention of the curious, let them tell me how we shall manage to make use of the knowledge heretofore acquired, if we do not begin by learning the language of the writers, and knowing to what objects the names employed by them belong. To admit therefore the study of Botany, and to reject that of the nomenclature, is a most absurd contradiction.

# BOTANY;

TO A LADY.

#### LETTER I.

ON THE FRUCTIFICATION AND LILIACEOUS PLANTS.

Dated the 22d of August 1771. THINK your idea of amusing the vivacity of your daughter a little, and exercifing her attention upon fuch agreeable and varied objects as plants, is excellent: though I should not have ventured to play the pedant fo far as to propose it of myself. Since however it comes from you, I approve it with all my heart, and will even affift you in it; convinced that, at all times of life, the study of nature abates the taste for frivolous amusements, prevents the tumult of the passions, and provides the mind with a nourishment which is salutary, by filling it with an object most worthy of its contemplations.

 $C_2$ 

You have begun with teaching your daughter the names of the common plants which you have about you; this was the very thing you should have done. The few plants which she knows by fight are fo many points of comparison for her to extend her knowledge: but they are not fufficient. You defire to have a little catalogue of the most common plants, with the marks by which they may be known. I find some difficulty in doing this for you: that is, in giving you thefe marks or characters in writing, after a manner that is clear, and at the same time not diffuse. This feems impossible without using the language peculiar to the subject; and the terms of that language form a vocabulary apart, which you cannot understand unless it be previously explained to you.

Besides, merely to be acquainted with plants by sight, and to know only their names, cannot but be too insipid a study for a genius like yours; and it may be presumed that your daughter would not be long amused with it. I propose that you should have some preliminary notions of the vegetable structure or organization of plants, in order that you may get some real information, though you were to take only a few steps into the most beautiful and the richest of the three kingdoms of nature. We have nothing therefore to do yet with the nomenclature, which is but

the knowledge of a Herbarist. I have always thought it possible to be a very great Botanist without knowing so much as one plant by name; and, without wishing to make your daughter a very great Botanist, I think nevertheless that it will always be useful to her to learn how to fee, whatever the looks at, well. Do not however be terrified at the undertaking: you will foon know that it is not a great one. There is nothing either complicated or difficult in what I have to propose to you. Nothing is required but to have patience to begin with the beginning. After that, you may go on no farther than you choose.

We are now getting towards the latter feafon, and those plants which are the most simple in their structure are already past. Besides, I expect you will take some time to make your observations a little regularly. However, in the mean while, till spring puts you in a situation to begin and sollow the order of nature, I am going to give you a few words of the vocabulary to get by heart.

A perfect plant is composed of a root, of a stem with its branches, of leaves, slower, and fruit, (for in Botany, by fruit, in herbs as well as in trees, we understand the whole sabric of the seed.) You know the whole of this already, at least enough to understand the term; but there is a principal part which requires an examination

Lily.

more at large; I mean the fructification, that is, the flower and the fruit. Let us begin with the flower, which comes first. In this part nature has enclosed the summary of her work; by this she perpetuates it, and this also is commonly the most brilliant of all parts of the vegetable, and al-

ways least liable to variations.

Take a lily<sup>a</sup>: I believe you will easily find it still in full flower. Before it opens, you fee at the top of the stem an oblong greenish bud, which grows whiter the nearer it is to opening; and when it is quite open, you perceive that the white cover takes the form of a basin or vase divided into several segments. This is called the corolla, and not the slower, as it is by the vulgar, because the flower is a composition of several parts, of which the corolla is only the principal.

The corolla of the lily is not of one piece, as you easily see. When it withers and falls, it separates into fix distinct pieces, which are called petals. Thus the corolla of the lily is composed of fix petals. A corolla confisting of several pieces like this is called a polypetalous corolla. If it

were

<sup>\*</sup> Lilium candium of Linnæus, (Pl. 1.) finely figured by Dr. Thornton, in n. 7. or any of its congeners, (fee L. Chalcedonicum & bulbiferum, figured in Curtis's Magazine, 30 and 36.) or almost any of the tribe of these which are called liliaceous flowers, and are for the greater part eminently beautiful. As Amaryllis formofisma. Curt. Mag. 47.

were all of one piece, like the bell-flower or bind-weeds, it would be called monope-

talous. But to return to our lily.

You will find exactly in the middle of the corolla a fort of little column rifing from the bottom, and pointing directly upwards. This, taken in its whole, is called the pistil or pointal: taken in its parts, it is divided into three; 1, the swollen base, with three blunted angles, called the germ or ovary; 2, a thread placed upon this, called the flyle; 3, the style crowned by a fort of capital with three notches: this

capital is called the stigma.

Between the piffil and the corolla you find fix other bodies entirely separate from each other, which are called the famens. Each stamen is composed of two parts, one long and thin, by which it is fastened to the bottom of the corolla, and called the filament; the other thicker, placed at the top of the filament, and called anthera or antherd. Each anther is a box which opens when it is ripe, and throws out a yellow dust, which has a strong smell; this is called pollen or farina.

b Campanula rotundifolia Linnæi.

Convolvulus sepium (Pl. 12. f. 3.) & arvensis,

&c. Linnæi. Flora rustica, t. 88, 89.

d The old English name of anthera is fummit; Grew called it semet.—The stigma has also been named fibula.

Such is the general analysis of the parts which constitute a flower. As the corolla fades and falls, the germ increases, and becomes an oblong triangular capsule, within which are flat seeds in three cells. This capsule considered as the cover of the

feeds, takes the name of pericarp.

The parts here mentioned are found in the flowers of most other plants, but in different proportion, fituation, and number. By the analogy of these parts, and their different combinations, the families of the vegetable kingdom are determined: and these analogies are connected with others in those parts of the plant which feem to have no relation to them. For instance, this number of fix stamens, sometimes only three, or fix petals or divisions of the corolla, and that triangular form of the germ, with its three cells, determine the liliaceous tribe; and in all this tribe, which is very numerous, the roots are bulbs of some fort or other. That of the lily is squamous, or composed of scales; in the asphodel, it is a number of oblong folid bulbs connected togethere; in the crocus, and faffron there are two bulbs, one over the other; in the colchicumf they are placed fide by fides.

The

<sup>\*</sup> As in the peony, potatoe, &c. These are called by fome tuberous roots,

Or meadow faffron.

s He might have added that some of these bulbs are

The lily, which I have chosen because it is in feafon, and also on account of the fize of the flower and its other parts, is deficient however in one of the constituent parts of a perfect flower, namely the calyx, which is that outer green part of the flower usually divided into five parts or composed of five small leaves; sustaining and embracing the corolla at the bottom, and enveloping it entirely before it opens, as you may have remarked in the rose. The calyx, which accompanies almost all other flowers, is wanting in the greater part of the liliaceous tribe; as the tulip, the hyacinth, the narcissus, the tuberose, &c. and even in the onion, leek, garlick, &c. which are also liliaceous, though they appear very different at first fight. You will perceive also that in this whole tribe the stems are simple and unbranched, the leaves entire, and never cut or divided: observations which confirm the analogy of the flower and fruit in this. family, by that of the other parts of the plants. If you bestow some attention upon these particulars, and make them familiar to you by frequent observations, you are already in a condition to determine, by an at-

folid like the turnip: others composed of coats, one over another, as in the onion. Linnæus does not allow them to be roots; and indeed it is only their being underground that led former Botanists to call them so. He names them bybernacula, winter germs or buds, into which the whole plant retires during the cold season.

tentive

tentive and continued inspection of a plant, whether it be of the liliaceous tribe or not: and this without knowing the name of the planth. You see that this is not a mere labour of the memory, but a study of obfervations and facts truly worthy of a naturalisti. You will not begin by telling your daughter all this at once; and you will be even more cautious, when in the fequel you shall be initiated in the mysteries of vegetation; but you will unveil to her by degrees no more than is suitable to her age and fex, by directing her how to find out things of herfelf, rather than by teaching herk. Adieu, my dear cousin; if all this trash be agreeable to you, I am at your fervice.

If it should happen to be spring when the reader takes up this letter, he may examine the snow-drop, crocus, dassodil, narcissus, crown imperial, tulip, lily of the valley, hyacinth, &c. always taking care, in the garden, to avoid double slowers. See Letter II.

Botany is frequently, but we fee here how unjuftly, represented as a science which depends wholly upon the memory, as if it were nothing but to get

the names of ten thousand plants by heart.

Rouffeau takes every occasion to inculcate this fundamental lesson of education; and indeed it cannot be inculcated too often. See Letter V.

### LETTER II.

ON CRUCIFORM FLOWERS.

The 18th of October 1771.

SINCE you understand so well, my dear cousin, the first lineaments of plants, though so slightly marked, as to be able already to distinguish the liliaceous family by their air; and since our little Botanist amuses herself with corollas and petals, I am going to set before you another tribe, upon which she may again exercise her little knowledge; with rather more difficulty I own, because the slowers are much smaller, and the soliage more varied, but with the same pleasure both on her side and on yours, at least if you have as much delight in sollowing this slowery path as I find in tracing it out to you.

When the first rays of spring shall have enlightened your progress, by shewing you in the gardens hyacinths, tulips, narcissuses, jonquils, and lilies of the valley, the analysis of all which is already known to you, other flowers will soon catch your attention, and require of you a new examination; such are stocks and rockets. Whenever you find

1 Cheiranthus incanus Linnæi. Plate 2.

m Hesperis matronalis Linnæi—Or if these are not at hand, wall-flowers, cabbage, turnip, cole-seed, mustard, charlock, radish, &c.

them double, do not meddle with them, they are disfigured; or, if you please, dressed after our fashion: nature will no longer be found among them; she resules to reproduce any thing from monsters thus mutilated: for if the most brilliant part of the flower, namely the corolla, be multiplied, it is at the expence of the more effential parts, which disappear under this addition of brilliancy.

Stock.

Take then a fingle flock gilliflower, or stock, as it is vulgarly called, and proceed to the analysis of the flower: you will perceive immediately an exterior part which was wanting in the liliaceous flowers, namely the calvx. This confifts of four pieces, which we must call leaves, leaslets, or folioles, having no proper names to express them by, as we have that of petals for the pieces which compose the corolla. These four pieces are commonly unequal by pairs; that is, there are two leaflets opposite and equal, of a smaller size, and two others also opposite and equal, but larger, especially towards the bottom, where they are so rounded as to exhibit a very sensible protuberance or bump on the outfide.

In this calyx you will find a corolla composed of four petals. I say nothing of their colour, because that makes no part of their character. Each of these petals is sastened to the receptacle, or bottom of the calyx, by a narrow pale part, which is called unguis, or the claw of the petal, and this

spreads

spreads out over the top of the calyx into a large, flat, coloured part, called *lamina*, or the *border*<sup>n</sup>.

In the centre of the corolla is one pissil, long and cylindric, or nearly so; chiefly composed of a germ ending in a very short style, and that terminated by an oblong stigma, which is bifid, that is to say, divided into two parts, which are restex or bent back on each side.

If you examine carefully the respective position of the calyx and corolla, you will see that each petal, instead of corresponding exactly to each leastet of the calyx, is, on the contrary, placed between two; so that it answers to the opening which separates them; and this alternate position has place in all flowers which have as many petals to the corolla as leastets to the calyx.

It remains now to speak of the stamens. You will find fix of them in the slower of the stock, as in the liliaceous slowers, but not all equal, or else alternately unequal, as in those; but you will perceive two opposite to each other, sensibly shorter than the other four which separate them, and which are also separate from each other in pairs.

I shall

<sup>&</sup>quot;I wonder that Rousseau says nothing of the regular structure of this corolla, the petals generally standing wide from each other, and forming a figure something like the cross of the order of St. Louis, whence these corollas are called cruciform, or cross-shaped.

I shall not enter here into a detail of their structure and position: but I give you notice that, if you look carefully, you will find the reason why these two stamens are shorter than the other four, and why two leastets of the calyx are more protuberant, or, as the Botanists speak, more gibbous, and the other two more flatted.

To finish the history of our stock; you must not abandon it as soon as you have analysed the slower, but wait till the corolla withers and falls, which it does pretty soon; and then remark what becomes of the pistil, composed, as we observed before, of the germ, the style, and the stigma. The germ grows considerably in length, and thickens a little as the fruit ripens. When it is ripe, it becomes a kind of slat pod, called slique.

This filique is composed of two valves, each covering a small cell: and the cells are separated by a thin partition. When the seed is ripe, the valves open from the bottom upwards to give it passage, and remain fast to the stigma at top. Then you may see the slat round seeds ranged along each side of the partition; and you will find that they are fastened alternately to right and lest by a short pedicle to the sutures, or each edge of the partition.

I am very much afraid, my dear coufin, that I have fatigued you a little with this long description; but it was necessary to give you the essential character of the nu-

merous

merous tribe of cruciform flowers, which forms an entire class in almost all the systems of Botanists: and I hope that this description, which it is difficult to understand here without a figure, will become more intelligible when you thall have gone through it with some attention, having at the same time the object before your eyes.

The great number of species in this class has determined Botanists to divide it into two sections, in which the flowers are persectly alike, but the fruits, pericarps, or

feed-veffels, are fenfibly different.

The first order comprehends the cruciform flowers with a silique, or pod, such as the stock, those mentioned in note (m), and the like.

The fecond contains those whose seed-vessel is a filicle, that is, a small and very short pod, almost as wide as it is long, and differently divided within; as whitlow-grass, mithridate-mustard, bastard-cress, &c. in the fields; and scurvy-grass, horse-radish, candy-tust, honesty, &c. in the gardens: though the seed-vessel of the last is very large, it is still a silicle, because the length exceeds the breadth very little. If none of these are known to you, I presume at least that you are acquainted with the

• See note (a).

P 287 species. In the 17th class, diadelphia, or two brotherhoods, 695; and in the 19th, sygenesia, 1247 species. These numbers, here and in the sequel, are given from the 14th edition of Systema Vegetabilium, by Chevalier Murray. In Willdenow's edition of the Species Plantarum, they are considerably increased.

Shepherd's

Shepherd's-purse, which is so common a weed in kitchen gardens. Well, then, coufin, this shepherd's-purse is of the cruciform tribe and silicle branch of it, and the form of the silicle is triangular. By this you may form some idea of the rest till they fall into your hands.

But it is time to let you breathe; I will only therefore give you a hint at prefent, that in this class, and many others, you will often find flowers much fmaller than those of the stock, and sometimes so small that you cannot examine their parts without the assistance of a glass; an instrument which a Botanist cannot do without, any more than he can without a needle, a lancet, or penknife, and a pair of good feiffars. Prefuming that your maternal zeal may carry you thus far, I fancy to myself a charming picture of my beautiful coufin bufy with her glass examining heaps of flowers, a hundred times less flourishing, less fresh, and less agreeable than herself. Adieu, dear cousin, till the next chapter.

<sup>q</sup> Fl. Dan. t. 729. Curt. Lond. 1. Ger. 276. 1.

<sup>r</sup> The young Botanist should be advertised that these filicles or little pods differ much in their form: some are flat, and round or oval; others are spherical or spheroidal, (see pl. 2. k. l.) and that of shepherd's-purse has a form peculiar to itself. Pl. 2. i.

s This of the smallness of the parts in many flowers is an objection that every idle novice makes to the Linnzan system, ever trembling lest any thorn or obstacle, be it ever so minute, should occur in the flowery path: the difficulty however will in great measure vanish, if he will but have patience to go regularly on his way.

## LETTER

OF PAPILIONACEOUS FLOWERS.

The 26th of May 1772

SINCE you continue, dear coufin, to pursue, with your daughter, that peaceable and delightful study which fills up those voids in our time too often dedicated by others to idleness, or something worse, with interesting observations on nature; I will resume the interrupted thread of our

vegetable tribes.

My intention is to describe fix of these tribes to you first, in order to render the general structure of the characteristic parts of plants familiar. You have already had two of them; there are four remaining, which you must still have the patience to go through, and after that, quitting for a time the other branches of that numerous race, and going on to examine the different parts of the fructification, we shall manage so, that without knowing many plants perhaps, you will at least never be in a strange country among the productions of the vegetable kingdom.

But I must inform you, that if you will take books in hand, and pursue the common nomenclature; with abundance of names, you will have few ideas, those

D which

which you have will be confused, and you will not follow properly either my steps or those of others; but will have at most a mere knowledge of words. I am jealous, dear cousin, of being your only guide in this part of Botany. When it is the proper time, I will point out to you the books that you may consult. In the mean while have patience to read nothing but in that of nature, and to keep wholly to my letters.

Pea.

Peast are, at present, in full fructification. Seize the moment to observe their characters: they are some of the most curious that Botany affords. One general division of flowers is into regular and irregular. The first are they whose parts all Ipring uniformly from the centre of the flower, and terminate in the circumference of a circle. This uniformity is the reason why, when we view flowers of this kind, we do not distinguish an under from an upper part, nor the right from the left; fuch are the two tribes which we have already examined. But you will fee at first fight that the flower of the pea is irregular, that you eafily diffinguish the longer part of the corolla, which should be at top, from the shorter, which should be at bottom; and you know very well, when you hold up the flower to the eye, whether it be in its natural fituation or not. Thus in examin-

<sup>&</sup>lt;sup>t</sup> See Plate 3, which is coloured red, to make the flower more conspicuous.

ing an irregular flower, whenever we speak of the top and the bottom, we suppose it to be in its natural fituation.

The flowers of this tribe being of a very particular structure, you must not only have feveral pea flowers, and diffect them fucceffively, to observe all their parts one after another, but you must also pursue the progress of the fructification from the first flowering to the maturity of the fruit.

First, you will find a monophyllous calyx; that is, one of an entire piece, ending in five very distinct points, the two wider of which are at top, and three narrower at bottom. This calyx bends towards the lower part, as does also the peduncle, or little stalk which supports it: this peduncle is very small and easily moveable; so that the flower readily avoids a current of air, and commonly turns its back to the wind and rain:

Having examined the calyx, you may pull it off, so as to leave the rest of the flower entire, and then you will fee plainly

that the corolla is polypetalous.

The first piece is a large petal, covering the others, and occupying the upper part of the corolla; it is called the standard, or banner. We must make use neither of our eyes nor of common sense, if we do not perceive that this petal is defigned to protect the other parts of the flower from the principal injuries of the weather. In tak-D 2

ing of the standard, you will observe, that it is inserted on each side by a little process into the side-pieces, so that it cannot be

driven out of its place by the wind.

The standard, being taken off, exposes to view those two side-pieces to which it adhered; they are called the wings. In taking these off, you will find them still more strongly inserted into the remaining part, so that they cannot be separated without some effort. These wings are scarcely less useful in protecting the sides of the slower,

than the standard in covering it.

Taking off the wings, you discover the last piece of the corolla; this is that which covers and defends the centre of the flower, and wraps it up, especially underneath, as carefully as the three other petals envelop the upper part and the sides. This last piece, which, on account of its form, is called the boat or keel, is, as it were, the strong-box into which nature has put her treasure, to keep it safe from the attacks of air and water.

When you have well examined this petal, draw it gently downwards, pinching it flightly by the keel or thin edge, for fear of tearing away what it contains. I am certain you will be pleafed with the mystery it reveals when the veil is removed.

The young fruit involved in the boat or keel is constructed in this manner: a cylindric membrane, terminated by ten dif-

tinct threads, furround the germ, or embryo of the legume or pod. These ten threads are so many filaments, united below round the germ, and terminated each by a yellow anther, whose farina covers the stigma which terminates the style, or grows along the side of it: this stigma, though yellow with the meal which sticks to it, is easily distinguished by its sigure and size. Thus do these ten silaments form also about the germ an interior armour, to preserve it from

exterior injuries.

If you examine more curioufly, you will find that these ten filaments are united into one at the base, only in appearance. For in the upper part of this cylinder there is a piece or stamen which at first appears to adhere to the rest, but as the flower fades and the fruit increases, separates, and leaves an opening at top, by which the fruit can extend itself by opening and separating the cylinder gradually; which otherwise, by compressing and straitening it all round, would impede its growth. If the flower is not fufficiently advanced, you will not find this stamen detached from the cylinder; but put a fine pin or needle into two little holes which you will fee near the receptacle at the base of that stamen, and you will foon perceive the stamen with its anther separate from the nine others, which will continue always to form one body, till at length they fade and dry, when the D 3

germ becomes a legume, and has no longer

any occasion for them.

This legume is diftinguished from the filique of the cruciform tribe, by the teeds being fastened to one side only of the case, alternately indeed to each valve of it; but all of them to the same side. You will understand this distinction perfectly if you open the pod of a pea and of a stock at the same time, taking care only to have them before they are quite ripe, that, when the pericarp is opened, the seeds may continue fastened by their proper ligaments to their sutures and their valves.

If I have made myfelf well understood, you will comprehend, dear cousin, what astonishing precautions have been heaped together by nature to bring the embryo of the pea to maturity; and, above all, to protect it, in the midst of the greatest rains, from that wet which is fatal to it, without inclosing it in a hard shell, which would have made it another kind of fruit. The Creator, attentive to the preservation of all beings, has taken great care to protect the fructification of plants from attacks that

<sup>&</sup>quot;In doing this you will also perceive that the legume is unilocular, or has one cell only; whereas you remember that the silique was said to be bilocular. And if you take a ripe legume, you will find that it opens by the upper future, opposite to that to which the feeds are sastened; whereas the silique opens from the bottom upwards by both sutures. Compare Pl. 3. 8. with Pl. 2. h.

may injure it; but he feems to have doubled his attention to those which serve for the nourishment of man and animals, as does the greater part of the leguminous or pulse tribe. The provision for the fructification of peas is, in different proportions, the same through this class. The flowers have the name of papilionaceous, from a fancied refemblance of them to the form of a butterfly (papilio); they have generally a standard or banner, two wings, and a boat or keel; that is, four irregular petals. But in fome genera the boat is divided longitudinally into two pieces; and these flowers have in reality five petals: others, as clover, have all their petals united, and, though papilionaceous, are however monopetalous flowers.

The papilionaceous or leguminous plants form one of the most numerous and useful tribes. Beans, peas, lucerne, saintsoin, clover, lupins, lentils, tares or vetches, indigo, liquorice, kidney-beans, all belong to it; the character of the last is to have the boat spirally twisted, which at first sight might be taken for an accident. There are also some trees belonging to it; among others that which is commonly called acacia, but which is not the true acacia, and many beautiful flowering shrubs. But of these more hereafter. Adieu, cousin, I wish well to every thing that you love.

v Trifolium pratense Linnæi.

w Robinia Pfeudacacia Linnæi.

### LETTER IV.

OF LABIATE AND PERSONATE FLOWERS.

The 19th of June 1772.

ET us talk of plants, my dear coufin, whilst the season for observing them invites us. Your folution of my question concerning the stamens of cruciform flowers is perfectly right, and shows that you have understood me, or rather attended to me; for you have nothing to do but to attend in order to understand. You have accounted very well for the fwelling of the two leaflets of the calyx, and the relative shortness of two of the stamens, in the stock, by the bending of these two stamens. One step more would have led you to the primary cause of this structure; for if you ask once more why these stamens are thus bent, and confequently shortened. I answer that you will find a little gland upon the receptacle, between the stamen and the germ; and it is this gland which, by throwing the stamen to a distance, and forcing it to take a round, necessarily shortens it. Upon the same receptacle are two other glands, one at the foot of each pair of longer stamens; but being on the outside of them, between these stamens and the calyx, they do not oblige them to bend,

and therefore do not shorten them: so that the two pairs of stamens stand higher than the two fingle bent ones; not because they are longer, but because they are straight. These four glands, or at least vestiges of them, are more or less visible in almost all cruciform flowers, and are much more diftinct in some than in the stock. If you ask me what the glands are for, I answer, that they are one of those instruments destined by nature to unite the vegetable to the animal kingdom, and to make them circulate from one to another. But laying these enquiries aside, in which we anticipate a little too much, let us, for the present, return to our tribes of plants.

The flowers which I have hitherto deferibed to you are polypetalous. I ought perhaps to have begun with the regular monopetalous flowers, which have a much more simple structure, but it was this very simplicity which discouraged me. They constitute rather a great nation than a single tribe; so that to comprehend them all under one common mark, we must employ characters so general and so vague, that, whilst we seem to say something, in effect we scarcely say any thing. It is better to confine ourselves within narrower bounds, which we can mark out with more precision.

Among

<sup>\*</sup> As in arabis turrita, cabbage, mustard, charlock, radish, &c.

Among the irregular monopetalous flowers, there is a tribe whose physiognomy is so marked, that we distinguish the members of it easily by their air. It is that to whose flowers Linnæus has given the name of ringent, because they are cut into two lips, the opening of which, whether natural or produced by a flight compression by the fingers, gives them the air of a gaping mouth. This tribe is divided into two branches: one of labiate or ringent flowers, properly so calledy; and the other of personate or masked flowers, the Latin word persona fignifying a mask. The character common to all the tribe is not only a monopetalous corolla, cut into two lips, the upper called the casque or belmet, the lower, the beard; but also four stamens almost in the same row, distinguished into two pairs, one longer, and the other shorter. The inspection of the object itself will explain these characters better to you than can be done in writing.

Dead-Nettle. Let us begin with the labiate flowers. For an example I should willingly give you sage, which is common in almost all gardens: but the singular structure of its stamens, which has occasioned some Botanists to separate it from the associates to which it naturally belongs, induces me to look for

y Plate 4. f. 1. b.

<sup>&</sup>lt;sup>2</sup> Plate 4. f. 2. a.

another instance in the white dead-nettle: which, notwithstanding its nameb, has no affinity with nettles, properly fo called, except in the shape of the leaves. This plant is fo common every where, and continues so long in flower, that it cannot be difficult for you to find itc. Without stopping here to consider the elegant situation of the flowersd, I will confine myfelf to their structure. The white deadnettle bears a monopetalous labiate corolla, with the casque or upper lip arched in order to cover the rest of the flower, and particularly the stamens, which keep, all four of them, very close under cover of its roof. You will eafily difcern the longer pair and the shorter pair, and in the midst of them the style, of the same colour, but distinguished from them by being forked at the end, instead of bearing an anther like the stamens. The beard or lower lip bends back, and hangs down, fo as to let you fee the infide of the corolla almost to the bottom. In this genus the lower lip is divided

<sup>&</sup>lt;sup>a</sup> Rosemary, with some few others not so well known, must also be avoided, because there are only two stamens to the flower.

b Lamium album Linnæi. Curtis II. 45. Pl. 4, f. i. Fl. Rust. t. 26.

c The largeness of the flowers also makes it proper for examination; but if the smell should be any objection, there is ground-ivy, with the other lamiums, betony, hearhound, baum, self-heal, baum of gilead, &c.

d Called verticillate, or whorled.

lengthwise in the middle, but that is not

general in this tribe.

If you pull out the corolla, you will take the stamens along with it, these being fastened by the filaments to that, and not to the receptacle, whereon the pistil only will remain. In examining how the stamens are fastened in other flowers, we find them generally attached to the corolla in monopetalous, and to the receptacle or calyx in polypetalous flowers: fo that in the latter case one may take away the petals without the stamens. From this observation we have an elegant, easy, and pretty certain rule to know whether a corolla confifts of one piece or feveral, when it is difficult, as it fometimes is, to be certain of it immediately.

The corolla, when pulled off, is open at bottom, because it was fastened to the receptacle, so as to leave a circular opening by which the pistil and what surrounds it may grow up within the tube. That which surrounds the pistil in this deadnettle, and all the labiate tribe, is the rudiment of the fruit, consisting of sour embryos, which become four seeds that are naked, that is, without any pericarp or covering; the monophyllous calyx divided into sive segments serving this purpose, so that the seeds, when they are ripe, are detached, and fall to the ground separately. This is the character of the labiate slowers.

The

The other branch or fection, which is that of the personate flowers, is distinguilhed from the former; first in having the two lips not usually open, or gaping, but closed and joinede, as you may see in the fnap-dragonf, a flower not uncommon in gardens; or for want of that, in the toad-flax, a vellow flower with a four, fo common in the country at this feafons. But a more precise and certain character is, that instead of having four naked feeds at the bottom of the calyx, like the labiate flowers, these have a capsule or case inclosing the feeds, and not opening till they are ripe, in order to disperse them. To these characters we may add that the greater part of the labiate plants are either strong smelling and aromatic, as marjoram, thyme, basil, mint, hyssop, lavender, &c. or elferstrong fmelling and stinking, as the dead-nettle, hedge-nettle, cat-mint, black hoarhoundh, &c. Some few only having little or no fmell, as bugle, felf-heal, and

e There are too many exceptions to this to form a general character, if under the idea of personate flowers we include all the plants in the second order of Linnæus's 14th class, as Rousseau seems to do.

f Antirrhinum majus Linnæi. Mill. fig. t. 42. pl. 4. f. 2.

g Antirrhinum Linaria Linnæi. Curtis I. 47. Fl. Ruft. t. 93.—It flowers later with us. Most of the personate tribe flower late.

h Here, and in some other places, I have taken the liberty of putting plants better known among us, instead of those which Rousseau has given.

hooded willow herb: whereas most of the plants with personate flowers are not odorous, as fnap-dragon, toad-flax, eye-bright, loufewort, yellow rattle, broom-rape, ivyleaved toad-flax, round-leaved toad-flax, fox-glove<sup>1</sup>, &c. I know of none that have a strong smell in this branch but the scrophularia, or figwort, which fmells ftrong, without being aromatic. Here I am not able to name any but fuch plants as may perhaps be unknown to you; but you will gradually get acquainted with them, and, whenever you fee them, you will be able by vourself to determine what class they belong to. I wish you would try to settle the branch or fection by its phyfiognomy, and that you would exercise yourself in judging at fight whether a flower be labiate or perfonate. The exterior form of the corolla may fuffice to guide you in this choice, which you may verify afterwards by pulling out the corolla, and looking at the bottom of the calyx; for, if you have judged right, the flower which you have named labiate will show you four naked seeds, and that which you have named personate will show you a pericarp: the contrary would prove that you were mistaken; and by a fecond examination of the same plant you would prevent a like mistake another

time.

Some of these have the mouth of the corolla gaping. See pl. 4. f. 3

timek. Here, dear cousin, is business cut out for several walks. I shall not fail to provide something for those that will succeed.

\* This advice will apply in all the other natural classes. From this passage it is clear that by labiate flowers Rousseau understands all that are included in the first order; by personate flowers, all that are in the second order of Linnæus's 14th class: but many of the flowers in the second order have the lips open. Pl. 4. 6. 3.

## LETTER V.

### OF UMBELLATE PLANTS.

The 16th of July 1772.

COMFORT yourself, my good cousin, for not having detected the glands in the cruciform flowers. Great Botanists, and quick-sighted ones too, have not been more happy. Tournefort himself makes no mention of them. They are obvious only in few genera, though we find vestiges of them in almost all; and it is by analyzing some of the cruciform flowers, and always observing inequalities in the receptacle, and then examining these inequalities, that we find out that these glands belong to most of the genera; and suppose therefore by analogy that they exist in the others, where we do not distinguish them.

I comprehend that you may not be pleased at taking so much pains, without knowing the names of the plants which you examine. But I own fairly that it did not enter into my plan to spare you that little chagrin. It is pretended that Botany is merely a science of words, which only exercises the memory, and teaches the names of plants. For my part, I know not any reasonable study which is a mere science of words: and to which of these shall

shall we give the name of Botanist to him who has a name or a phrafe ready when he fees a plant, but without knowing any thing of its structure; or to him who, being well acquainted with this structure, is ignorant nevertheless of the arbitrary name which the plant has in this or that country? If we give our children nothing but an amusing employment, we lose the best half of our defign, which is, at the same time that we amuse them, to exercise their understandings, and to accustom them to attention. Before we teach them to name what they fee, let us begin by teaching them how to fee. This science, which is forgot in all forts of education, should make the most important part of it. I can never repeat it often enough; teach them not to pay themfelves in words, nor to think they know any thing of what is merely laid up in their memory.

However, not to play the rogue with you too much, I give you the names of some plants, with which you may easily verify my descriptions, by causing them to be shewn you. For instance, if you cannot find a white dead-nettle, when you are reading the analysis of the labiate or ringent slowers, you have nothing to do but to send to an herbarist for it fresh gathered, to apply my description to the flower; and then having examined the other parts of the plant, in the manner which I shall hereaster.

point out, you will be infinitely better acquainted with the white dead-nettle, than the herbarist who furnished you with it will ever be during his whole life. In a little time, however, we shall learn how to do without the herbarist; but first we must finish the examination of our tribes. And now I come to the fifth, which, at this

time, is in full fructification.

Figure to yourfelf a long stem, pretty straight, with leaves placed alternately upon it, generally cut fine, and embracing at the base, branches which grow from their ala, or axils1. From the upper part of this stem, as from a centre, grow several pedicles or rays, which spreading circularly and regularly, like the ribs of an umbrella. crown the stem with a kind of basin, more or less open<sup>m</sup>. Sometimes these rays leave a fort of void in the middle, and represent, in that case, more exactly the hollow of a basin: sometimes also this middle is furnished with other rays that are shorter. which, rifing less obliquely, form with the others nearly the figure of a half sphere with the convex fide uppermost.

Each of these rays is terminated, not by a flower, but by another set of smaller rays, crowning each of the former exactly as the

first crown the stem.

The angles formed by a leaf or branch with the stem.

The figure is that of an inverted cone. Pl. 5.

f. 1, 2. Pl. 13. Ill marks the transfer of the state of the

Here then are two similar and successive ranks: one of large rays, terminating the stem; another of smaller rays, like the others; each of them terminating the great ones.

The rays of the little umbels are no farther subdivided, but each of them is the pedicle to a little flower, of which we shall

speak presently.

If you can frame an idea of the figure which I have just described, you will understand the disposition of the flowers in the tribe of umbelliferous or umbellate plants: umbella being the Latin word for an umbrella.

Though this regular disposition of the fructification be striking, and sufficiently constant in all the umbellate plants, it is not that however which constitutes the character of the tribe. This is taken from the structure of the flower itself, which must therefore be described.

But it is expedient, for the fake of greater clearness, to give you in this place a general distinction with regard to the relative disposition of the flower and fruit in all plants; a distinction which extremely facilitates their methodical arrangement, whatever system you adopt for that purpose.

The greater number of plants, as the

<sup>&</sup>quot; Linnæus calls the first the univerfal, and the second set the partial, umbel, or umbellule.

pinko, for instance, have the germ inclosed within the flower; these are called inferior flowers, as inclosing or being below the

Many, however, have the germ placed below the flower, as in the rose?; for the hep, which is the fruit of it, is that green tunid body which you fee under the calyx, and this with the corolla crowns the germ, and does not envelop it, as in the former case; such are called superior flowers, as being above the germ.

The umbellate plants have a superior flower. The corolla has five petals, called regular, though frequently the two outmost petals of the flowers at the extremity of the umbel are larger than the three others.

The form of these petals varies in the different genera, but it is usually cordate or heart-shaped. They are very narrow next the germ, but gradually widen towards the end, which is emarginate, or flightly notched; or else they finish in a point, which, being folded back, gives the petal the air. of being emarginate.

Between each petal is a stamen, and the anther generally standing out beyond the corolla; the five stamens are more visible:

Or jasmine, rosemary, sage, borage, primrose, plum, cherry; all the ringent, cruciform, and papilionaceous, tribes; all the compound flowers, &c.

P Scabious, honeyfuckle, currant, gooseberry, elder, Inowdrop, narriffus, hawthorn, pear, apple, &c.

<sup>9</sup> See Pl. 5. f. 5.

than the five petals. I make no mention here of the calyx, because it is not very

distinct in the umbellate plants.

From the centre of the flower arise two styles, each furnished with its stigma, and sufficiently apparent; these are permanent, or continue, after the petals and stamens fall off, to crown the fruit.

The most usual figure of this fruit is an oblong oval; when ripe it opens in the middle, and is divided into two naked seeds fastened to the pedicle, which, with an art that merits our admiration, divides in two, as well as the fruit, and keeps the seed separately suspended till they fall.

All these proportions vary in the different genera, but this is the most common order. It requires a very attentive eye to distinguish accurately objects so minute without a glass; but they are so deserving of attention, that

we cannot regret the trouble of it.

This then is the proper character of the umbellate tribe. A fuperior corolla, of five petals, five stamens, two styles, upon a naked fruit composed of two seeds growing

together. Ant !

Whenever you find these characters united in one fructification, be sure that the plant is of this tribe, even though in other respects it should have nothing in its arrangement of the order before laid down. And if you should find all this order conformable to my description, and see it how-

 $\mathbf{E}_{3}$  ever

ever contradicted by the examination of the flower, be fure that you are deceived.

For instance: if it should happen that, after having read my letter you should walk out and find an elder in flower, I am almost certain that at first fight you would say, here is an umbellate plant. In looking at it, you would find a large or universal umbel, a small or partial umbel, little white flowers, a superior corolla, and five stamens; it is certainly an umbellate plant, fay you. But let us see; let us take a flower.

In the first place, instead of five petals, I find a corolla divided into five parts indeed, but all of one piece. Now the flowers of umbellate plants are not monopetalous. There are five stamens, but I see no styles; and I more often see three stigmas than two. more often three feeds than two. Now the umbellate plants have never more or less than two stigmas, and two seeds to each flower. Lastly, the fruit of the elder is a foft berry, and that of the umbellate tribe dry and naked. The elder then is not an umbellate plant.

If now you go back and inspect with more accuracy the disposition of the flowers, you will fee that the elder has the structure of the umbellate tribe only in appearance. Though the principal rays proceed from the fame centre, the smaller ones are irregular, and the flowers are borne on a fecond subdivision: in short, the whole has not that order and regularity which we find in the umbellate plants. The arrangement of the flowers in the elder is called a *cyme*. Thus, by making a blunder sometimes, we learn to see with more accuracy.

Eryngo, on the contrary, has little or Eryngo. nothing the air of an umbelliferous plant, and yet it is one, because it has all the characters of the fructification. If you were by the sea side, you would easily know it by the bluish colour of the leaves, by their prickliness, and by the smooth membranous consistence of them like parchment. But this plant is uncommon in other situations, is rough and untractable, has not beauty enough to make you amends for the wounds it will give you in examining it; and, though it were ever so beautiful, my little cousin would soon be disgusted at handling so ill-humoured a plant.

The umbelliferous tribe is numerous, and fo natural, that it is very difficult to distinguish the genera: they are relations, whom we often take for each other, on account of their great resemblance. To affist us in distinguishing them, principal differences are noticed which are sometimes useful, but which we must not depend upon too much. The focus of the rays, both in the larger or

E 4 univerfal,

Eryngo is also very common by road-sides in France, but not with us.

univerfal, and in the smaller or partial umbel, is not always naked; it is sometimes surrounded with small leaves. This set of small leaves or folloles is called the *involucre*.

When it is placed at the origin of the universal umbel, it is named the universal involucre; and when at the origin of the partial umbel, it is named the partial involucre. This gives rise to three sections of umbellate plants.

1. Those which have both involucres.

2. Those which have partial involucres only.

3. Those which have neither.

There feems a fourth division wanting of those which have an universal involucre only; but there is no genus which is con-

fantly former more more than a property of

Your aftonishing progress, my dear coufin, and unwearied patience, have emboldened me so much, that, not regarding your sufferings, I have ventured to describe the umbellate plants, without fixing your eyes upon any model, which must needs have rendered your attention much more fatiguing. I am certain, however, that, reading as you do, after you have looked over my letter once or twice, an umbellate plant in flower will not escape you: and at this season you cannot fail finding many, both in the gardens and the fields.

Most of them have their little flowers white. As the carrot, chervil, parsley,

hemlock,

hemlock, fool's parsley, angelica, cow-parsnep, water-parsnep, burnet saxifrage, pignuts, cow-weed, &c<sup>t</sup>.

Some, as fennel, dill, parfnep, have yellow flowers; there are fome few with reddifh flowers, but none of any other colour.

Here, you will tell me, may be a good general notion of umbellate plants; but how will all this vague knowledge enfure me from confounding fool's parfley with true parsley or chervil, which you have mentioned all together? "The meanest kitchen-maid will know more of this matter than we with all our learning. You are right. But however, if we begin with observations in detail, we shall soon be overwhelmed with the number of them; our memory will abandon us, and we shall be loft the first step we make in this vast region; whereas, if we begin with knowing the great roads well, we shall feldom be lost in the bye-paths, and shall always find our way again without much trouble. Let us, however, admit an exception in favour of the utility of the object, and let us not expose ourselves, whilst we are analyzing the vegetable kingdom, to eat fool's parfley with our meat, or in our foup, through mere ignorance.

This plant, which is fo common a weed

t Here, and in other places, I fet down the names of our English Floras.

<sup>&</sup>lt;sup>n</sup> See Pl. 5. f. 1, 2, 3.

in gardens, is of the umbellate tribe, as well as parfley and chervil. It has a white flower as well as they'; it is in the fame fection with the latter, among those which have the partial, and not the universal, involucre; it is so like them in its foliage that it is not easy to mark the difference in writing. But here follow characters sufficient to prevent you from being mistaken.

Fool's Parsley. You must consider these plants when they are all in slower; for in that state only they have their proper character. The sool's parsley (æthusa cynapium) has under every partial umbel an involucre of three narrow, long, pointed sollioles, all placed on the outer part of the umbel, and hanging down; whereas the sollioles of the partial umbels in the chervil surround it entirely, and grow equally on every side: and as to parsley, it has only a few short sollioles, sine almost as hairs, and distributed indifferently at the base of both umbels.

When you are very certain of the fool's parsley in flower, you will confirm your-felf in your judgment by slightly bruising and smelling its foliage; for the disagree-

The flower of parsley is yellowish. But the flowers appear yellow in many of the umbellate plants, from the germ and anthers being so, though the corolla is white. Rousseau.—The germ and anthers also are frequently large in proportion to the fize of these minute flowers, and the corolla easily falls off, especially with wet.

able venemous smell will no longer suffer you to confound it with parsley or chervil, which have both rather a pleafant smell. Very certain at length not to make a miftake, you will examine these three plants together and separately in every state, and in all their parts, especially in their foliage, which accompanies them more constantly than the flower; and by this examination, compared and repeated till you have acquired certainty at fight, you will be able to know and distinguish them without the least trouble. Thus does study bring us to the very door of practice; after which the latter confers the facility of knowing things.

Take breath, dear cousin, for this is an unconscionable letter; and yet I dare not promise you more discretion in the next; after that, however, we shall have nothing before us but a path bordered with flowers. You deserve a garland for the chearfulness and perseverance with which you have condescended to follow me through these briars, without being discouraged at their

thorns.

## LETTER VI.

OF COMPOUND FLOWERS.

May the 22d 1773.

HOUGH there be still, dear cousin, a great deal wanting to complete our idea of the five former tribes of plants, and I have not always known how to adapt my descriptions to the understanding of our young Botanist; I flatter myself, however, that I have given you fuch an idea of them, as to enable you, after fome months herbarization, to render the air, port, or babit, of each tribe familiar to you: fo that, when you see a plant, you may conjecture nearly whether it belong to one of these five tribes, and to which; provided always that, by an analysis of the fructification. you afterwards fee whether you may not have been deceived in your conjecture. The umbellate plants, for instance, have thrown you into some embarrassment, from which, however, you may eafily escape when you please, by means of the hints which I subjoined to my descriptions. In short, carrots and parsneps are so common, that nothing is easier in the middle of summer than for the gardener to fend you one or other of them in flower out of the kitchen-garden. Now from the mere view of an umbel.

umbel, and the plant which bears it, you must acquire so clear an idea of the umbellate tribe, that you will rarely be deceived at first fight, whenever you meet with one. This is all that I have hitherto pretended; for we have nothing to do yet with genera and species; and I repeat it once more, that it is not the nomenclature of a parrot which I wish you to acquire, but a real science, and one of the most delightful sciences that it is possible to cultivate. I go on, therefore, to our fixth tribe before I take a more methodical road. It may perhaps at first embarrass you as much, if not more, than the umbellate plants. But my defign at prefent is nothing more than to give you a general notion of it, especially as we have still plenty of time before the generality of these plants are in full flower; and the interval, well employed, will fmooth those difficulties against which we have not strength to contend.

Take one of those little flowers which, Daisy, at this season, cover all the pastures, and which every body knows by the name of daisy. "Look at it well; for, by its appearance, I am sure you will be surprised when I tell you, that this flower, which is so small and delicate, is really composed of between two and three hundred other flowers, all of them perfect; that is, hav-

ing each its corolla, germ, pistil, stamens, and feed; in a word, as perfect in its species as a flower of the hyacinth or lily. Every one of those leaves which are white above and red underneath, and form a kind of crown round the flower, appearing to be nothing more than little petals, are in reality fo many true flowers; and every one of those tiny yellow things also which you see in the centre, and which at first you have perhaps taken for nothing but stamens, are real flowers. If your fingers were already exercised in botanical diffections, and you were armed with a good glass and plenty of patience, I might convince you of the truth of this; but at prefent you must begin, if you please, by believing me on my word, for fear of fatiguing your attention upon atoms. However, to put you at least in the way, pull out one of the white leaves from the flower: you will think at first that it is flat from one end to the other; but look carefully at the end by which it was fastened to the flower, and you will fee that it is not flat, but round and hollow in form of a tube, and that a little thread ending in two horns iffues from the tube; this thread is the forked style of the flower, which, as you now fee, is flat only at top.

Now look at those little yellow things in the middle of the flower, and which, as I have told you, are all so many flowers; if the flower be sufficiently advanced, you

will

will fee feveral of them open in the middle,

and even cut into several parts.

These are monopetalous corollas, which expand; and a glass will easily discover in them the pistil, and even the anthers with which it is furrounded. Commonly the yellow florets towards the centre are still rounded and closed. These, however, are flowers like the others, but not yet open; for they expand fuccessively from the edge inwards. This is enough to show you by the eye the possibility that all these small affairs, both white and yellow, may be fo many distinct flowers; and this is a constant fact. You perceive, nevertheless, that all these little flowers are pressed, and inclosed in a calyx, which is common to them all, and which is that of the daify. In confidering then the whole daify as one flower, we give it a very fignificant name, when we call it a compound flower. Now there are many genera and species of flowers formed, like the daify, of an affemblage of other smaller flowers, contained in a common calyx. This is what constitutes the fixth tribe, of which I proposed to treat; namely, that of the compound flowers.

Let us begin by avoiding all ambiguity with regard to the word flower, which we may do in the present case, by restraining it to the compound flower, and giving the

name of floscules or florets to the little component flowers; but in the midit of this verbal precision let us not forget that each of these florets is a genuine flower.

You have observed two forts of florets in the daify: the yellow ones, which occupy the middle or disk of the flower, and the little white tongues or straps which surround them.

The former are fomething like the flowers of the lily of the valley, or hyacinth in miniature: and the latter bear fome resemblance to those of the honeysuckle. We shall leave to the first the name of florets<sup>2</sup>; and to distinguish the second we shall call them femisforets<sup>2</sup>: for in reality they have a little the air of monopetalous flowers gnawed off on one side, and having scarcely half the corolla remaining.

These two forts of florets are combined in the compound flowers in such a manner, as to divide the whole tribe into three sec-

tions, very distinct from each other.

The first section counsts of those which are entirely composed of semi-florets, both in the middle and circumference; these are called semi-fielculous flowers, and the whole is always or one colour, which is generally yellow. Such is the common dandelion,

<sup>7</sup> Pl. 6: f. 1. c. e. f. 2. b. f. 3. b.

<sup>&</sup>lt;sup>2</sup> Pl. 6. f. i. e. & f. 3. b.

<sup>&</sup>lt;sup>a</sup> Linnæus also calls these ligulate florets, from ligula a strap. Pl. 6. f. 1. c. & f. 2; b.

ь РІ. 6. f. 2.

the lettuce and fowthistle; the succory and endive, which have blue flowers; the scor-

zonera, falfafy, &c.

The second section comprehends the flosculous flowers, or such as are composed of florets only: "these are also commonly of one colour; as immortal flowers, burdock, wormwood, mugwort, thistles, and artichoke, which is nearly allied to them: it is the calyx of this that we suck, and the receptacle that we eat, whilst it is yet young, before the flower opens, or is even formed. The choke which we take out of the middle, is an affemblage of florets which are beginning to be formed, and are separated from each other by long hairs fixed in the receptacle.

The third section is of flowers composed of both these. They are always so arranged that the florets occupy the centre of the flower, and the semi-florets the circumserence, as you have seen in the daisy. The flowers of this section are called radiate. Botanists have given the name of ray to the set of semi-florets which compose the circumserence; and of disk to the area or centre of the flower occupied by the florets. This name of disk is sometimes given to the surface of the receptacle in which all the florets and semi-florets are fixed. In the radiate flowers the disk is often of one co-

<sup>&</sup>lt;sup>6</sup> Pl. 6. f. 3. <sup>4</sup> Pl. 6. f. 1. & Pl. 26. F

lour, and the ray of another; there are, however, genera and species in which both are alike.

Let us endeavour now to fix in your mind an idea of a compound flower. The common clover is in blow at this feafon; 'the flower is purple: if you should take one in hand, feeing fo many little flowers affembled, you might be tempted to take the whole for a compound flower. You would however be mistaken. In what? fay you. Why, in supposing that an afsemblage of many little flowers is sufficient to constitute a compound flower; whereas, besides this, one or two parts of the fructification must be common to them all; so that every one must have a part in it, and no one have its own separately: these two parts in common are the calyx and receptacle. The flower of the clover indeed, or rather the group of flowers which has the appearance of being but one flower, feems at first to be placed upon a fort of calyx; but remove this pretended calyx a little, and you will perceive that it does not belong to the flower, but that it is fastened below it to the pedicle that bears it. This then is a calyx only in appearance; but in reality it belongs to the foliage, not to the flower: and this supposed compound flower is only an affemblage of very small leguminous or

papilionaceous flowers, each of which has its distinct calyx, and they have nothing common to them but their being fastened to the same pedicle. Vulgarly all this is taken for one flower; it is a false idea however, or, if we must look upon it as such, we must at least not call it a compound, but an aggregate or capitate flower, or a head of flowers; and these terms are sometimes so applied by botanical writers.

This, dear cousin, is the most simple and natural notion I can give you of this numerous class of compound flowers, and the three sections into which it is subdivided. I now come to the structure of the fructish-cations peculiar to this class, and this perhaps will bring us to determine the character of

it with more precision.

The most effential part of a compound flower is the receptacle; upon which are placed first the florets and semi-florets, and then the seeds which succeed them. This receptacle, which forms a disk of some extent, makes the centre of the calyx, as you may see in the dandelion, which we will here take as an instance. The calyx in this tribe is commonly divided into several parts, down to the base, that it may close, open again, and turn back, as it does during the progress of the fructification, without being torn. The calyx of the dandelion is formed of two rows of sollioles inserted into each

f Pl. 6. f. 1. b. & 26. e.

other; and the follioles of the outer row turn back and curl downwards towards the pedicle, whilft the follioles of the inner row continue straight, to surround and hold in the semi-florets composing the flower.

One of the most common forms also of the calyx in this class is the *imbricate*, or that which is made up of several rows of follioles, lying over each other like tiles on a roof. The artichoke, blue-bottle, knapweeds, and scorzoneras, may serve as in-

stances of imbricate calyxes.

The florets and semi-florets inclosed within the calyx are placed very thick upon the disk or receptacle, in form of a quincunx, or the checks upon a chess-board. Sometimes they touch each other without any thing interposed between them; sometimes they are separated by partitions of hairs, or small scales, which continue fast to the receptacle after the seeds are fallen. You are now in the way to observe the differences of calyxes and receptacles; we will go on then to the structure of florets, and semi-florets, beginning with the former.

A floret<sup>g</sup> is a monopetalous flower, commonly regular, with the corolla divided at top into four or five parts. The five filaments of the stamens are fastened to the tube of this corolla: they are united at top into a little round tube, which surrounds the pistil; and this tube is the five anthers

g Pl. 6. f. 1, e. f. 3. b.—Pl. 25. f. 2. c.—Pl. 26. d. united united circularly into one body. This union of the anthers, according to modern botanists, forms the effential characters of compound flowers, and belongs to their florets only, exclusive of all others. If therefore you find several flowers upon the same disk, as in the scabiouses and teasels, unless the anthers are united in a tube round the pistil, and the corolla stands upon one naked feed, fuch flowers are not florets, nor do they form a compound flowerh. On the contrary, whenever you find in a fingle flower the anthers thus united, and a fuperior corolla on a fingle feed, this flower, though fole, is a genuine floret, and belongs to the compound tribe; for it is better thus to take the character from a precise structure than from a deceitful appearance.

The pistil has the style generally longer than the sloret, above which it rises through the tube formed by the anthers. It is most frequently terminated at top by a forked stigma, the two curling horns of which are very visible. The pistil does not rest upon the receptacle any more than the sloret, but both upon the germ, which serves them as a base, and grows and lengthens as the sloret withers, becoming in time a longish seed, remaining sastened to the receptacle till it is ripe: then it falls, if it be naked; or the wind wasts it to a distance if it be crowned with an egret of seathers or hairs; and the

h See Pla xi. f. 1.

receptacle remains quite naked in some genera, but is surnished with scales or hairs in others.

The structure of the semi-florets is like that of the florets; the stamens, the pistil, and the seed, are arranged almost in the same manner; only in the radiate flowers there are many genera, wherein the semi-florets of the ray are apt to be abortive, either because they have no pistils, or because those which they have are barren: in such cases the flower seeds only by the florets in the middlek.

In the whole compound class the seed is always sessile, that is, it bears immediately upon the receptacle without any intermediate pedicle. But there are seeds in which the down or egret which crowns them is sessile; and others in which it is fastened to the seed by a pedicle. You understand that the use of this down is to spread the seeds about to a distance, by giving the air more hold upon them.

To these irregular impersect descriptions I should add that the calyx has generally the property of opening when the flower expands; of closing when the florets fall off, in order to confine the young seed, and to hinder it from falling before it is ripe; and,

110001

<sup>27.</sup> f. 2. e. of it is proved to a state of

k Sunflower.

Thistles, artichoke. See Pl. 25. f. 2. c.

Market Lettuce, dandelion. See Pl. 25. f. 1. d.

lastly, of opening again and turning quite back to give a larger area to the seeds which increase in size as they grow ripe. You must often have seen the dandelion in this state, when children gather it, to blow off the down that forms a ball round the reverted calvx.

To understand this class well, you must follow the flowers from before their expanfion to the full maturity of the fruit; and in this fuccession you will see transformations and a chain of wonders, which will keep every fenfible mind that observes them in a continual admiration. One flower proper for these observations is the sunflower, which is radiate; as are also ox-eye, Chinese after, and many others, which are the ornament of the borders in autumn. I have already faid that there are thistles for the flosculous and fcorzonera and dandelion for the femiflosculous flowers. All these are large enough to be diffected, and studied with the naked eye, without fatiguing yourfelf too much.

I will not trouble you at present any more upon the tribe or class of compound flowers. I tremble already at having abused your patience too much by details which would have been clearer if I had known how to make them shorter; but it is impossible for me to avoid the difficulty arising from the smallness of objects. Adieu, dear cousin!

4 LET-

# LETTER VII.

#### OF FRUIT TREES. .

ERE, dear cousin, you have the names of those plants which you sent me last. I have put a mark of interrogation to those which I had any doubt of, because you had not taken care to put the leaves with the flower, and they are often necessary to determine the species, especially to so slender a Botanist as I am. When you arrive at Fourriere you will find most of the fruit-trees in flower; and I remember you requested some directions from me upon this article. At present I can only give you some hints upon the subject, because I am very busy; and yet I would not have you lose the season for this examination.

You must not, my dear friend, give more importance to Botany than it really has; it is a study of pure curiosity, and has no other real use than that which a thinking sensible being may deduce from the observation of nature and the wonders of the universe.

Man has changed the nature of many things to convert them better to his own use; in that he is not to be blamed: but then it is nevertheless true that he has often disfigured them, and that, when he thinks he is studying nature in the works of his own hands, he is frequently mistaken. This

error is found above all in civil fociety; but it has a place also in gardens. The double flowers, which we admire so much in our borders and beds, are but monsters, deprived of the power of producing their like; a power with which nature has endowed every organized being. Fruit-trees are somewhat in the same case, by being ingrafted; you may plant the pips or feeds of pears and apples of the best sorts, but they will produce nothing but wildings. To know then the pear and the apple of nature, you must not look for them in orchards, but in woods. The flesh or pulp is not so large and succulent, but the feeds ripen better, multiply more, and the trees are vastly bigger, and more vigorous. But I am entering on a fubject that would carry me too far-Let us return to the orchard.

Our fruit-trees, though ingrafted, preferve all the botanical characters which diftinguish them; and it is by an attentive confideration of these characters, as well as by the transformation of the graft, that we ascertain there being but one species of pear, for instance, under a thousand different names, by which the shape and taste of their fruits have caused them to be distinguished into so many pretended species, which are at bottom but varieties: nay more, the pear and apple are only two forts or species of the same kind or genus, and their only characteristic difference is, that the stalk of the apple

apple enters into a hollow in the fruit, and that of the pear is fastened to the narrow part of a fruit a little lengthened out". In the same manner the different forts of cherries are nothing but varieties of the fame ipecies; all the plums are but one species of plum; nay the genus of prunus or plum contains three principal species; the plum properly fo called, the cherry, and the apricot, which also is only a species of plum. Thus when the learned Linnæus, in dividing the genus into its species, has enumerated the domestic plum, the plum cherry, and the plum apricoto; ignorant people have laughed at him, but observers have admired the justness of his arrangement.

The fruit-trees belong mostly to a numerous tribe, which has a character not difficult to seize; the stamens which are many in number, instead of arising from the receptacle, are fastened to the calyx, Peither immediately, or with the corolla, which is

n Nor is this always confiant, some pears having the common shape of the apple. It is extremely difficult to find any permanent differences between fruits which are diffinguished by every body at first sight. We may add, however, that the corollas of the pear are white, those of the apple red on the outside: the apple also has a firmer pulp, and none of those tubercles which some forts of pear have: and, lastly, the leaves of the pear are very smooth; those of the apple more rounded, less ferrated, and villous underneath.

o 1. Prunus domestica. 2. Prunus Cerasus. 3. Prunus Armeniaca. The fruit-trees are figured by Duhamel.

PPl. 18. f. 1. c. and f. 2.

polypetalous, and confifts commonly of five petals. The following are characters of

some of the principal genera.

The pear, comprehending also the apple and the quince, has the calyx monophyllous, divided into five fegments; the corolla of five petals fastened to the calyx, about twenty stamens, all fastened likewise to the calyx. The germ is inferior, and there are five styles. The fruit, as every body knows, is slessly, and has sive cells containing the feeds.

The genus plum, comprehending the apricot and cherry, as was before observed, and also the laurel, has the calyx, corolla, and stamens, nearly as in the pear. But the germ is superior, or within the corolla; and there is but one style. The fruit is rather watery than sleshy, and contains a stone.

The genus almond, including the peach and nectarine, is almost like the plum; but the germ has a down upon it, and the fruit, which every body knows is succulent in the peach, and dry in the almond, incloses a hard stone, which is rough and full of cavites.

All this is very roughly sketched out, but I hope contains enough to amuse you for the present. Adieu, dear cousin!

<sup>&</sup>lt;sup>q</sup> Befides those mentioned above, this class, called icosandria by Linnæus, contains other fruits, as the pomegranate, service, medlar, raspberry, strawberry, &c.

## LETTER VIII.

OF MAKING A HORTUS SICCUS, OR HERBARIUM.

April the 11th, 1773.

HE earth, dear cousin, begins to put on its green robe, the trees to bud, the flowers to open; some are even already past; an instant of delay would be the loss of a whole year for Botany:—I proceed then

without farther preamble.

I fear we have hitherto treated our subject in too abstract a way, by not having applied our ideas to determinate objects; it is a fault which I have been guilty of, especially in the umbellate tribe. If I had begun by fetting one of them before your eyes, I should have spared you a very fatiguing application to an imaginary object, as well as a very difficult description to myself, and such as a fingle look would have supplied. Unfortunately, at a distance to which the law of necessity restrains me, I am not able to deliver the objects into your hand; but provided each of us can see with the same eyes, we shall understand one another very well, when we relate what we fee. The whole difficulty is, that the indication must come from you; for to fend you dried plants from hence, would be doing nothing. To know

know a plant well, you must begin with feeing it growing. A hortus ficcus, or herbarium, by which Latin terms we call a collection of dried plants, may serve to put us in mind of the plants we have once known; but it gives us only a poor knowledge of those we have never seen before. You therefore must send me such plants as you wish to know, and have gathered yourfelf; and it is my bufiness to name, class, and describe them; till, by comparative ideas, become familiar to your eye and your understanding, you arrive at classing, arranging, and naming, by yourfelf, those which you fee for the first time: and this is the science which distinguishes the true Botanist from the mere Herbarist or Nomenclator. My defign then here is to teach you how to prepare, dry, and preferve plants, or specimens of plants, in such a manner as that they may be eafily known and determined. In a word, I propose to you to begin a hortus ficcus. Here is a deal of business preparing at a distance for our little Botanist; for at present, and for some time to come, the address of your fingers must supply the weakness of hers.

First, here is some provision to be made; namely, five or six quires of gray paper, and almost as many of white, of the same bigness, pretty strong and well sized, without which the specimens would rot in the gray paper, the plants, or at least the flow-

ers, would lose their colour, and this, of all the parts, is that by which they are most easily known, and which it is most pleafant to see in a collection of dried plants. It were also to be wished that you had a press of the same size with your paper, or at least two pieces of board well planed, between which you may keep your papers and specimens, pressed by stones, or any other weight with which you may load the upper plank. When you have made these preparations, you must observe the following rules, in order to prepare your plants so as to preserve them and know them again.

The precise time to gather your plant is when it is in full flower, or rather when some of the flowers begin to fall, to give place to the fruit, which begins to make its appearance. It is at this time, when all parts of the fructification are visible, that you must endeavour to gather the plant in

order to dry it.

Small plants may be taken whole with their roots, which must be brushed, that no earth may remain. If the earth be wet, it must either be dried, that it may be brushed, or else the root must be washed; but in this case you should wipe it well, and dry it before you put it into the papers, without which it would infallibly rot and injure the

plants.

r See Dr. Withering's Arrangements of British Plants, edit. 2. Introd. p. 45.

plants near it. You need not, however, preferve the roots, unless they have some remarkable singularities; for in most plants the branching sibrous roots are so alike, that it is not worth the trouble. Nature, which has done so much for elegance and ornament, in the form and colour of plants, in whatever strikes our sight, has destined the roots entirely to useful functions; because, being concealed within the earth, to give them an agreeable structure would have

been to hide a light under a bushel.

Trees and all great plants can only be had by specimens: but then that specimen should be so well chosen as to contain all the constituent parts of the genus and species, that it may suffice to know and determine the plant from whence it is taken. It is not fufficient that all the parts of the fructification are distinguishable, which would be enough to determine the genus; but the character of the foliation and ramification also must be sufficiently visible: that is, the origin and form of the leaves and branches, and even, as much as may be, some portion of the main stem itself; for, as you will fee in the fequel, all this ferves to distinguish the species of the same genus, which are perfectly alike in the flower and fruit. If the branches are too thick, they may be made thinner, by cutting them with a sharp knife nicely underneath, as much as may be, without cutting

and mutilating the leaves. There are Botanists who have the patience to slit the bark, and draw the wood out so nicely, that when the bark is united again, the branch feems to be entire though the wood is gone: by which means, there are none of those inequalities and bumps which spoil and diffigure a collection, and give a bad form to the plants. Where the flowers and leaves do not come out at the same time, or grow too far distant from each other, you will take a little branch in flower, and another in leaf, and placing them together on the fame leaf of your book, you thus have before you different parts of the same plant, fufficient to give you a complete knowledge of it. As to plants where you find only the leaves, the flower being either past or not yet come, you must wait with patience till they show their faces, to be fully acquainted with them; a plant being no more certainly to be known by its foliage than a man by his clothes.

Such is the choice that you should make in what you gather; you must have a choice also as to the time in which you do it. Plants gathered in the morning before the dew is off, or in the evening when it is damp, or in the day-time when it is wet, will not keep. You must absolutely choose a dry season, and even then the driest and hottest time of the day, which in summer, is between eleven in the morning and five in the afternoon. Even then, if you find the least moisture on them, you must not take them, for they will certainly not keep.

When you have gathered your specimens, you must bring them home as soon as you can, quite dry, to put and arrange them in your papers. For this purpose you lay down at least one sheet of gray paper, upon this half a sheet of white paper, and then your plant, taking great care that all the parts of it, especially the leaves and flowers, are well opened, and laid out in their natural fituation. If the plant be a little withered, without being too much fo, it will generally fpread out better upon the paper, with the fingers and thumb. But there are rebellious plants which frart up on one fide. whilst you are ranging them on the other. To prevent this inconvenience, I have leads, halfpence, and farthings, which I place upon those parts that I have just put in order, whilst I am arranging the rest, so that when I have done, my plant is almost covered with these pieces, which keep it in its proper fituation. Then you place another half-sheet of white paper upon the first, pressing it with your hand, to keep the plant in the position you have given it, bringing your left hand that presses gradually forward. and at the same time taking away the leads, &c. with your right; then put another sheet of gray paper upon the second white paper, all the while pressing the plant, lest

it lose the position you have given it: upon the gray paper place another half sheet of white, as before; upon this another plant arranged and covered like the former, till you have placed your whole harvest, which ought not to be too numerous at once; both that your task may not be too laborious, and that your paper may not contract too much humidity during the drying; which would infallibly spoil your plants, unless you hastened to change the papers with the same attention as before; this, however, is what you must do from time to time, till your specimens have taken their

bent, and are all very dry.

Your pile of plants and papers thus arranged, must be put into the press, without which your plants will not be flat and even; fome are for preffing them more, others less; experience will teach you this, as well as how often the papers should be changed. without taking unnecessary pains. Lastly, when your plants are quite dry, put each of them separately into a sheet of paper, one upon another, without other papers between, for which there is no occasion, and you will thus begin a hortus siccus, which will continually increase with your knowledge, and at length contain the hiftory of all the vegetation of the country. Take care always to keep your collection very close, and a little pressed; without which the plants, however dry they might be.

be, will attract the humidity of the air, and

again get out of form.

Now the use of all these pains is to arrive at a knowledge of each particular plant, and to understand one another well when we talk of them.

For this purpose you must gather two specimens of each plant; one larger to be kept, the other smaller to send me. You must number them carefully, so that both great and little specimen shall always have the fame number. When you have a dozen or two of species thus dried, you will fend them to me in a little parcel by the first opportunity. I will fend you back their names and descriptions; by means of the numbers you will know them in your collection, and after that in their natural state, wherein, I presume, you first examined them. This is the certain way to make as fecure and rapid a progress as you can, at a distance from your guide.

P. S. I forgot to tell you that the same papers may serve over and over again, provided you take care to air and dry them well. I should also add here, that your hortus siccus must be kept in the driest part of the house, and rather on the first than the ground-sloor.

## LETTER IX.

EXPLANATION OF THE CLASSES LINNÆAN SYSTEM.

March the 25th, 1774.

Have received all your packets very fafe, and cannot but admire the neatness with which you have arranged your plants; the care you have taken in having all the parts necessary to determine both the genus and species in your specimens; and the brilliancy of colour in most of the flowers. All this ferves to fhow how much better the female fingers are adapted to fuch operations than ours. I am pleafed also to hear that our little Botanist had so large a share in laying out and drying these plants, which I shall carefully preserve as a memorial of the industry and adroitness of both. But what gives me the most pleasure is, to see that you have remarked, with fo much fuccess in general, to which of the natural classes your plants belong: so that I am well convinced you have profited by my lessons, and have paid a due attention to my letters.

What reward, dear cousin, can I give you for your unwearied patience and perseverance in following me through fo much

abstract

abstract matter, when your curiofity must needs have been piqued, and your defire of being acquainted with the rank and names of the beautiful objects which you gathered, arranged, and dried, with so much affection, must have been awakened? I have now, in fome degree, endeavoured to content you, by the paper which accompanies this, containing the names of all the plants in your packets, placed after the numbers which you have put to them in your collection: fo that to the common objects which you knew by rote, you are now enabled to add a confiderable number, whose acquaintance you will value more, because you know them upon thorough examination. You have, therefore, so many more points to rest upon: but this is not fufficient; you cannot be a Botanist till you are able to help yourself, to cast me off entirely, and to find out a plant with which you are unacquainted. All this, however, will still require some time and patience; and as you remember that you are not to take any more steps in this kingdom than are agreeable, you will inform me when you are tired.

Such information I purpose now to convey to you by degrees: and having initiated you by showing how you may determine the class of some plants, I will now open the whole mystery, and instruct you how to determine the class of them all. To do

G 3 www.snniJ lethis

this you must learn a system; in which, however, you are not to expect that all vegetables are arranged in natural classes, such as I have hitherto explained to you, but after an artificial method, the order of nature not being in all points yet unveiled to our mortal eyes. Your pains, however, will not have been thrown away; because I promise you that our artificial system shall preserve the natural tribes which you have studied so well.

Do not fuffer yourself to be terrified at the word system. I promise you there shall be little difficulty in it to you who have patience and attention; and as little parade of hard words as possible, only allowing me to name my classes and orders. The system I propose to you is not the French one by Tournesort, which is very beautiful, and has great merit; but the Swedish one by Linnæus. I prefer this, because it is most complete, and most in fashion.

You are so well acquainted with all the constituent parts of the fructification, that you need not be told what the stamens and pissils are. Linnæus has sounded his classes upon the former, and many of his orders upon the latter of these. But at present

the

The English student will find great advantage in possessing many elementary books, explaining all the terms, in his own language. Now also he has Linnæus's system of vegetables and genera translated. Hudfon's Flora Anglica, Smith's Flora Britannica, and Withering's Arrangement, connect the English names with those of Linnæus.

the classes will furnish you with sufficient

employment.

I suppose you take a plant in hand that is in full flower; the first thing you have to fee is, whether the flowers are complete or perfect, that is, have both stamens and pistils. If so, view the stamens well, in order to discover whether they are entirely feparate from the piftil and each other from top to bottom, or united in some part or other: if they are separate, of the same, or an indeterminate length, and less in number than twenty, then the number alone will fuffice to determine the class; and those which have one stamen will belong to the first class entitled monandria; those with two stamens to the second, diandria; those with three to the third, triandria, and fo on to the tenth, entitled decandrias. These are Greek names, and fome of them not short ones: since, however, they are only four-and-twenty in all, you will indulge me fo far in time as to have them by heart. The flowers for examination should be gathered as nearly as possible in their natural state; for many of those which are cultivated in gardens undergo strange transformations, and either lose the stamens and pistils entirely, or acquire an additional number. The first classes, which have but few stamens, are not so liable to change as

Plates 7. to 16, with Pl. 5. & 1.

G 4 those

those which have many. Thus the number in the three classes already mentioned is not variable; nor in the fourth class, tetrandria. In the fifth, pentandria, some plants have more than their proper quota of stamens to the flower, at least when cultivated in gardens; but this is a very numerous class, and it is no wonder if we find some few irregular among so many. To secure you in some measure against mistakes on this and other occasions, I must observe, that nature in general carries a certain proportion through all the parts of the fame work; and therefore if you have a flower which has a calyx divided into five fegments, and a corolla confifting of five petals, or divided into five parts; if you count fix or feven stamens, be fure all is not right, and take the pains to inspect some other flowers of the fame species, before you determine. I dare affirm such examination will convince you that your flower belongs to the fifth class, pentandria, in which the natural number of framens is five. In the fixth class, hexandria, whose beautiful flowers have fix stamens, I do not observe to considerable a variation as one might expect in plants that are fo much the objects of culture; you will however frequently count more than fix stamens in the flowers of the tulip. The flowers of the class heptandria should have seven stamens; but you will often find those of the horsechefnut

chefnut faulty in this respect: as you will also some flowers in the three following classes, octandria which has eight, enneandria which has nine, and decandria which has ten stamens, as the names all imply. With a little attention however to the proportion of the parts, and by a repetition of your examination where any doubt arises, you will find these ten classes easy to determine.

No flowers being known at present that have constantly and regularly eleven stamens, the eleventh class in the system of Linnæus contains those which have twelve; and is therefore entitled dodecandria. But the genera which have this precise number being few; and, as I observed before, the number being uncertain when the stamens are many, all plants are comprehended in this class that have any number of stamens, from eleven to nineteen inclusive, provided they are disfunited.

All plants that have more separate stamens than these belong to one of the two sollowing classes. Here then you must take in another consideration, besides the number of the stamens, to determine in which of these two classes you are to search for your plant. This consideration is, the situation of the stamens; which in the class icosandria is either on the calvx or corolla, and

u Plate 17.

in the thirteenth, polyandria, on the base or receptacle of the flower". This difference of fituation is only to be attended to in those flowers which have many stamens; for you will frequently observe in the fifth class that the monopetalous flowers have the stamens growing out of the corolla; but this circumstance has nothing to do in determining their class. The twelfth class has its name, icofandria, from the flowers in it having usually twenty stamens or thereabouts, at least in the greater part of the genera: this circumstance, however, is not to determine the class; but all plants which have many stamens, that is, more than nineteen, fastened either immediately, or mediately by means of the claws of the petals, to the calyx, are to be referred to the class icosandria. To affist you farther in distinguithing the flowers of this from those of the following class, it may be remarked that the calyx in this is monophyllous or all of one piece, and concave; and the corolla is fixed by its claw or fmall end into the calyx, instead of the base or bottom of the flower, as it generally is in the other classes.

When on the contrary you find more than nineteen detached stamens in the same flower, with a pistil or pistils, and situated on the base or receptacle of the slower, that plant must belong to the class polyandria, fignifying many stamens, and the stamens may vary in number from twenty to a thoufand in the different genera. These also either have a polyphyllous calyx, that is, consisting of several folioles, generally sive, or none at all; though sometimes it falls off, as in the poppy, when the slower opens.

We have hitherto supposed you to find all the stamens of the same length, or nearly fo: or if not, still we presume that you have not found a certain regular and determinate proportion in their lengths. Now, on the contrary, we suppose you to take up a flower which has an appearance of regularity in its whole structure; and that, on an attentive examination, you discover four stamens, not all equal in length, but ranged in one row, and the inner pair shorter than the outer one. This plant will probably belong to the fourteenth class, the name of which is didynamia\*, fignifying that two of the stamens are stronger than the others. Here you will immediately perceive that you are got among your old acquaintance, for it will strike you that all the flowers which have the character just described are either labiate or personate, and therefore that you were mistress of the class didynamia, before you knew that it had this Greek namey. All then that I need fay to you is, that Linnæus makes the effential character

F Plates 20. & 4.
y See Letter IV.

to confift, in the proportional arrangement of four stamens above expressed, accompanied with one pistil, and invested with

an irregular monopetalous corolla.

There is yet another class of these plants with proportional stamens, which, though you do not know it by the dreadful long name tetradynamia, is however one of your first acquaintance under the gentler appellation of cruciform flowers. These, you remember, have four stamens longer than the other two: this is the classical character, and hence its name. For the other distinctive marks by which this class is readily known at first fight, you have them at your fingers ends.

You are now in possession of all those classes which have the stamens free, separate, disunited. If a flower that has both stamens and pistils should present itself, in which you find the stamens united at bottom, it certainly belongs to one of the three next classes: and if, on the contrary, they are united at top, that is, the anthers form one body, it will belong to the nineteenth

class.

In the fixteenth class, called monodelphia, the filaments are united so as to form one regular membrane at bottom, whilst they are distinct at top. Of this character you have a clear and convincing instance in

<sup>3</sup> See Letter II. Plates 21. and 2.

<sup>2</sup> Plate 22.

that very common plant the mallow. In fome others, however, of this class, the character is not so evident, and without a careful inspection of the flowers to the very bottom, you might eafily be tempted to give them to another class. Observe then farther, that the flower has always a calyx, and frequently a double one: that the corolla confifts of five heart-shaped petals; that the receptacle of the fruit, as it is called, or the column to which the feeds are fastened, projects above them in the centre of the flower: that the germs furround this in a ring: that all the styles are united at bottom and form one body with the receptacle, but are divided at top into as many threads as there are germs: and that thefe germs grow into a kind of capfule divided into as many cells as there are pistils, or confisting of the same number of arils, which are loofe coats covering each feed feparately, and not eafily falling from it.

In the seventeenth class, diadelphia, the filaments are united at bottom: not however into one, but two bodies. These flowers also have but one pistil; the fruit is a legume or pod; and if I add that the flowers are papilionaceous, you will immediately discover that this is another class with which you are persectly acquainted, and with the form of whose flowers you were

fo much delightedb.

b See Letter III. Plates 23. and 3.

In the eighteenth class the filaments are united in three or more bundles, and the name of it is polyadelphia. The union being generally at the bottom only, without extending up the filaments, and the flowers having no distinguishing character, you must pull out the stamens, in order to be certain that the plant belongs to this class. The names of the three last-mentioned classes signify literally one, two, and

many brotherhoods.

If instead of the filaments being joined at bottom, they are free and distinct, but the anthers are connected together, so as to form one body, then your plant will be found in the class syngenesia. But the flowers in this class being small, and the abovementioned circumstance not being the first that will strike an examiner of flowers, it must be added that they are compound; and this one word is sufficient to overcome the whole difficulty with you who know these flowers at first sight, and have so frequently diffected the florets and semi-florets which compose them<sup>d</sup>.

Though in the four last classes the stamens have been in some sort united, yet both in these, and in all the sormer, they have been sound detached from the pistil, so at least as that the one may be taken off from the plant without the other. But what if a

c Plate 24.

Hower

d See Letter VII. and Plates 25. to 29, & Pl. 6. Syngenesia signifies congeneration, or union of the anthers.

flower should occur to you in which you are unable to do this, but you find on the contrary that the stamens grow upon the pissil itself? Then, I answer, it belongs to a class entitled gynandriae, which is the twentieth in the system of Linnæus, and derives its name from this peculiar circumstance, by which it stands insulated as it were, and detached from all the others. From the position of the pissils in this class arises a singularity in the appearance and shape of the slowers in most of the genera; and sometimes the receptacle is lengthened out in form of a style, and bears both stamens and pissils upon it.

Hitherto you have been concerned with fuch plants only as have flowers which I call complete or perfect, because they have both stamens and pissils. But a plant perhaps may have occurred to your observation in which you have found these parts always in separate, distinct flowers. In this case I beg leave to coin two words, and to call those which have only the stamens staminiferous, and those which have only the pistils pissilferous flowers. Now when you find these, and these only on the same tree or plant, that tree or plant belongs to the twenty-first class in the arrangement of Linnæus, called by him mon-

e Plate 30. and Dr. Thornton, Plate of the Blue Paffion flower.

f As in the common Arum, Curtis, Lond. 2 Mill. fig. 52. 1. J. Mill. illustr. Ger. 834. 1.

flowers of different kinds being produced in the fame habitation, or in the fame individual plant. Whereas in the following class, these staminiserous and pistilliserous slowers are not merely separate from each other, but are always found on distinct plants of the same species, and in other respects so alike, as not to be distinguished when they are out of flower. The name of this class therefore is diæciah, signifying two houses, and implying that incomplete flowers only are found in different habitations, or on separate trees or plants, never on the same.

There remains now only one possible case to provide for, in the arrangement of confpicuous flowers, which is this. Suppose you find some flowers that are complete, and at the same time others which bear only stamens or pistils, on the same plant with the complete flowers, or on different plants of the same species; there is a class, namely, the twenty-third, provided for the reception of such plants, and it is entitled polygamia,

from this variety in the flowersk.

For plants with inconspicuous flowers, as being of less consideration, there is only one class provided, and that is called *cryptoga*-

Plate 31. Alab h Plate 32. 100 / Plate 33.

<sup>\*</sup> Thunberg, and some others, have sunk the four classes from Gynandria to Polygamia, melting the species into other classes. I shall not dispute the propriety or convenience of this reformation: but it is my design to explain the system of Linnæus, as the great author himself delivered it.

mial, from the circumstance of the fructification being concealed, or not obvious to our eyes. For the flowers in the most perfect of these are hardly to be distinguished without a glass, and in many not even with it; nay, the most acute observers have not detected flowers in them all, though in all probability there is no vegetable without them. They will be easily known from plants with conspicuous flowers, by their singular Aructure; as you will readily acknowledge when I inform you that the objects of this, the lowest class of vegetables, are ferns, moffes, fea weeds, and fungufes: and therefore when we talk of inconspicuous flowers we do not mean to include fuch as are deftitute of a magnificent corolla, but fuch only as have not the stamens and pistils visible to the naked eye. But you are too good an obferver to require fuch admonitions. By this time you are doubtless sufficiently fatigued, as well as myself, with all this dry matter; and what is worse, you have not learnt to find out one plant; but patience, we are in the way, and have made great progress, though we are not arrived at the end of our journey. We will foon make another long stage, unless you tell me you have enough, and in that case I promise to trouble you no more with this trash: if it does not amuse and even interest you, throw it at once into the fire.

Plate 35 to 38.

## LETTER X.

EXPLANATION OF THE ORDERS IN THE LINNÆAN SYSTEM.

May the 1st, 1774.

RESUMING, dear cousin, that you have already examined abundance of spring flowers, and determined their classes, upon the instructions contained in my last letter, I shall proceed in this to give you the characters of the orders, or divisions of the classes. If you were to proceed at once to the examination of the species, all would be confusion; just as if you attempted to estimate a vast mixed multitude, fluctuating in tumultuary disorder: but if you have patience to make a regular progress; to throw this multitude into large bodies, to subdivide these into smaller ones, and these again into others fo fmall as to command them well with the eye, you have at length a regular army, which you can number, arrange, and discipline at your pleasure. We will now divide our twenty-four regiments into their respective companies. Here I think you will not find so much difficulty as in the classes: for the orders in the first thirteen classes are founded wholly upon the number of the pistils, so that the chief of your task here will be to learn so many

many new terms, which are formed by putting gynia instead of andria to the Greek words signifying the numbers: as monogynia, one pistil; digynia, two pistils; and so on.

After the first thirteen classes, we no longer use the pistils for the purpose of subdividing the classes into orders. In the class didynamia it would be nugatory, because you have observed that all the flowers of the ringent tribe have one pistil, and no more. Here then we have recourse to another circumstance which answers extremely well. For we find that most of the plants which have a labiate flower have four naked feeds at the bottom of the calyx; and that the perfonate flowers are succeeded by a capfule containing many small seeds: hence arises an elegant, commodious, obvious, and natural division of the fourteenth class into two orders, gymnospermia" and angiospermia"; the first containing all the ringent flowers with four naked feeds ripening in the calyx; the fecond, fuch as have the feeds contained in a bilocular pericarp, or feed vessel of two cells, and fastened to a receptacle in the middle of it.

In the next class, tetradynamia, the flowers have also one pistil, and no more. Here again it is found convenient to take the fruit

m Plate 20 f. 1. & Pl. 4 f. 1.
Plate 20 f. 2. & Pl. 4 f. 2, 3.
H 2

for the subdivision of it into orders. These are called siliculosa and siliquosa, from the form of the fruit, which we call silicle and silique; having only the word pod current in our language, which will not suffice to distinguish these from each other, nor from the pod in the leguminous tribe. The plants of the first order then have a silicle or short roundish pericarp; those of the second, a silique or oblong narrow pericarp: both are billocular; but the structure has been already sufficiently explained.

In the 16, 17th, and 18th classes, it is found best to take the orders from the number of stamens. Here then is no fort of difficulty; and, what is very pleasant, you have no new terms to burthen the memory.

The chief difficulty, with respect to the orders, lies in the class syngenesia. Tournefort's division of the compound flowers into flosculous, semi-flosculous, and radiate, was pretty and obvious; but Linnæus's is abstruse and difficult. I will explain it to you, however, as clearly as I can. You are perfect mistress of a compound flower, and the different sorts of florets of which it is composed. I must next inform you, therefore, that what you know by the name of compound is called by Linnæus a flosculous flower; and that he calls the florets, tubus-

o Plate 2. i, k, l.

9 See Letter II.

P Plates 21 & 2.

See Letter VI.

lous floscules, and the semi-florets, ligulate floscules: this being premised, we may use the language of Linnæus or Tournefort as we pleafe Now if you examine these floscules nicely, you will discover that they have fometimes both stamens and pistil; but you will fee that others have stamens only; others again a pistil only: and lastly, some have neither stamens nor pistil. The first of these I call perfects sloscules, the fecond framiniferous, the third pistilliferous, and the fourth neuter floscules. All these variations are to be found both in the tubulous and ligulate floscules; and must be well attended to, because on these variations, assisted by the form of the florets. Linnæus has founded the four first orders of this class.

Polygamia æqualist is the name of the first order. Polygamia is the family name, which this has in common with all the orders except the last; it is used only in opposition to monogamia, and implies that there are many florets inclosed within one common calyx; which is your idea of a compound stower. The peculiar name æqualis signifies equal, regular, or alike, and implies that the whole slower is regular, and that all the component sloscules therefore, whether tubulous or ligulate, are alike; and indeed they are not only so,

Pl. 6. f. 2. & 25. f. 2.

<sup>&</sup>lt;sup>a</sup> Perfect at least in appearance, if not always really so.

but likewise perfect, or all furnished with stamens and pital; and therefore each solowed by a seed. If these slowers have any ligulate floscules, all the rest are so; if any tubulous sloscules, all the rest are so likewise, except in two genera. Attractylis and Barnadesia, which have radiate flowers.

In the second order, Folygamia superflua, . all the florets of the disk, centre or middle of the flower are perfect; those of the ray or exterior part pistilliferous: both of them produce feed. Most of the flowers in this order are radiate, and then they are casily known by the circumstance of having fertile feeds both in the disk and ray: but there are some which have tubulous florets only, and appear like the disk of a radiate flower, as a daify would look when spoiled of its white femi-florets; whence Ray called them discoid flowers: in these, however, on an attentive inspection, you will discover that some of the outer ones are deficient in stamens at least, if not in corolla too. These are by much the largest orders, each of them containing almost double the number of genera that are in the three remaining orders of compound flowers taken together,

The third order of these compound flowers, or of the class syngenesia, is entitled fustranea. The character of the order is, that the florets in the disk or centre are

Pl. 6. f. 1. & pl. 26.

v Pl. 27. f. 1. perfect, perfect, and produce feed: whilst those of the ray are imperfect, and therefore abortive or frustrate; whence the name. This is a very small order, containing only eight genera; of which seven have radiate flowers, and the eighth, which however is a numerous one, has capitate flowers like the thistles, but differing from them in having either neuter or abortive florets next the calyx, as in the common blue bottle; in which the neuter floscules distinguish themselves by being much larger than the others: but on examination they are mere corolla, and nothing else.

In the fourth order, necessaria, the florets in the disk or middle are apparently perfect, but are not really so, and therefore produce no perfect seed; whilst the pistilliserous floscules in the ray or outside of the flower are fertile. All these have radiate flowers, except in two genera, wherein the exterior fertile florets have scarcely any corolla.

In the fifth order, Polygamia segregatax, there is a common calyx, as in the foregoing orders; but besides that, there is in this order a partial one, including one or more florets, which are thus separated from each other in a manner different from the rest of the orders: and hence the name. By this order the compound approach the aggregate flowers, such as the teasel, scabious, &c.;

w Pl. 27. f. 2. × Pl. 28.

but then these have not the character of the class *fyngenesia* in the union of the anthers.

The fixth or last order is entitled simply monogamia, because it consists of plants with simple, not compound flowers; which circumstance is abundantly sufficient to discriminate this order, provided you attend at the same time to the classical character.

We have now, dear cousin, happily, I hope, passed the fool's bridge, and are arrived safely on the other side, where the way is plain, and we shall toon get pleasantly to the end of our stage. In short, the orders of the three following classes, gynandria, monæcia, and diæcia, being sounded upon the stamens, and taking their names from the foregoing classes, according to the number and union or disunion of the stamens in the respective slowers, there is nothing new to be learnt in any of these.

The twenty-third class indeed, polygamia, has three orders, arising from the triple mode in which the three forts of flowers may be arranged; either on the same plant, on two distinct plants, or on three. When the perfect and imperfect flowers are on the same plant, the order is entitled monacia. When the perfect flowers are on one plant, and the imperfect ones on a second of the

<sup>7</sup> Pl. 29.—The violets are a good instance of this order.

<sup>\*</sup> Plate 33. Acer or maple.

same species, the order is then entitled diacia<sup>3</sup>. And when the perfect flowers are on one plant, staminiferous ones on a second, and pistilliferous ones on a third, all of the fame species, then such plant belongs to an order called triæciab, fignifying three houses; the three forts of flowers having three diftine habitations

. The last class having no flowers whose parts are difcernible by the naked eye, and therefore called cryptogamia-having also many genera in which we are uncertain what the fructification is-many in which we can differn no fructification at all-the characters of the orders can no longer be taken from the stamens and pistils. Fortunately the plants of this class have a very particular structure, serving very well both to ascertain the classical character, and the division of it into four orders; which are called, I. Filices, or Ferns. II. Musci, or Mosses. III. Alga, or Sea-weeds; and. IV. Fungi, or Funguses. Some modern authors have separated the horse-tails and a few other plants from the Ferns: and Marchantia, Jungermannia, &c. from the Algæ: thus making fix orders of this class.

The ferns mostly have their fructification upon the backs of their leaves. This. when examined by the microscope, appears

a The ash is an instance of this order.

b As in the fig.

c Plate 35.

to confist of a scale arising from the leaf, and opening on one side; and under that some little balls on pedicles, surrounded by an elastic ring: in due time the balls burst, and throw out a fine dust, which is supposed to be the seed. Linnæus makes the scale to be a calyx: and the globules are probably so many capsules or pericarps.

The mosses have small threads growing out of the bosoms of the leaves, terminated by a small body, the whole resembling stamens: accompanied by little shorter threads supposed to be pistils, sometimes on the same plant with the former, and sometimes on another. The first of these Linnæus took for anthers, and actually called them so; but he suspected them afterwards to be capsules, and such they turn out to be, on a narrower inspection with greater magnifiers.

Of the algee we know too little about the fructification to give a regular character of the order, which includes not only the feaweeds, but the liverworts, &c. There have been ranged by others among the mosses. In the liverworts there are little bodies visible enough, which are taken for staminiferous and pistilliferous flowers, distinct from each other: but experiments are yet wanting to ascertain them with precision. On the sea-weeds are little bladders, some hol-

low with hairs within, others filled with a gelly like substance; and these are supposed to be the flowers and fruits.

If the fungules have any fructification, it is imagined to be underneath, in the gills, pores, &c. But I will not detain you with these dregs of vegetable nature, in which you will take no pleasure, till you have imbibed an enthusiastic passion for Botany.

After the class cryptogamia, Linnæus has given the palms, in a twenty-fifth class, or appendix, without any character. I prefume he has thus thrown them into the rear. of his tystem, partly because he could not have arranged this proud fet of trees according to his laws, without tearing them from each other, and partly because they have not been examined with fufficient accuracy. You will scarcely have an opportunity of examining this natural class, the most remarkable characters of which are, that the staminiferous flowers are distinct from the piftilliferous, on the same or different individuals; except in one genus, which has complete or perfect flowers accompanied by staminiferous ones on the same individual, all proceeding from a spathe or sheath, and growing upon a spadix<sup>g</sup>. So that these trees belong to the three last classes of conspicuous flowers in the artificial system.

Thus,

f Plate 38.

The spadix is the receptacle in this tribe, and has no English name. In another place, Linnæus, in distributing vegetables into nine nations, affigns the first

Thus, dear cousin, we have accomplished our fecond stage. And this letter not being of so unconscionable a length as the former. I have accompanied it with two tables; one of the classical characters, and another explaining those of the orders: that, after reading my diffute explanation, you may have the whole under your eye at once; and thus perhaps at one view form a better idea of the arrangement of vegetables into classes and orders, than you could do from many detached pages. We are not yet arrived at specific or individual information; but we are on the borders, as I shall convince you in my next letter. In the mean time you have sufficient employment for your eyes and attention, without doors as well as within: for, if you had taken up this trash of mine only in your dreffing room, you would long fince have thrown it into the fire: if it meets with a better fate, I owe it merely to the beautiful objects which your fair hands have cropt in the garden and fields. Always give the preference to the latter where you can, both for the sake of exercise and having your plants in their natural state. Adieu, dear coufin ; continue your kind indulgence to my prate.

to the palms, calling them Princes of India, bearing their fructification on a fpadix within a fpathe; flowing; remarkable for their prodigious height; distinguished by an unvaried, undivided, perennial trunk; crowned at top by an evergreen bush of leaves; rich in abundance of large, fine fruit.

## The Outlines of LINNÆUS'S System of Vegetables.

A. Plants with conspicuous Flowers.

B. 1. All complete, or furnished with Stamen and Pistil.

C. With Stamens separate from the Pistil.
D. And separate from each other.

E. All of the same length, or not proportionably longer than each other.

F. In which the number only is to be confidered.

I. Monandria. One Stamen. II. Diandria. Two Stamens.

III. TRIANDRIA. Three Stamens.

IV. TETRANDRIA. Four equal Stamens.

V. PENTANDRIA. Five Stamens.

VI. HEXANDRIA. Six equal Stamens.

VII. HEPTANDRIA. Seven Stamens.

VIII. OCTANDRIA. Eight Stamens.

IX. Enneandria. Nine Stamens.

X. DECANDRIA. Ten Stamens.

XI. Dodecandria. From 11 to 19 Stamens inclusive.

F. In which the fituation is also to be confidered.

XII. ICOSANDRIA. About 20 Stamens on the Calyx or Corolla.

XIII. POLYANDRIA. Twenty Stamens or more on the Receptacle or Base of the Flower.

E. Some Stamens proportionably longer than others.

XIV. DIDYNAMIA. Four Stamens, two longer. One Pistil. Flowers ringent.

XV. TETRADYNAMIA. Six Stamens, four longer. One Pistil. Flowers cruciform.

D. Stamens coherent at bottom only, or by the Filaments.

XVI. Monadelphia. Filaments united into one body.

XVII. DIADELPHIA. Filaments in two bodies. Corolla papilionaceous.

XVIII. POLYDELPHIA. Filaments in 3 or more parcels.

D. Stamens coherent at top only, or by the Anthers.

XIX. SYNGENESIA. Anthers united, 5 Filam. distinct, 1 Pistil, Flowers compound.

C. With Stamens growing out of the Pistil itself.

XX. GYNANDRIA. Stamens on the Pistil, not on the Receptacle.

B. 2. All incomplete; or which have Stamens only, or Piffils only.

XXI. Monoecia. Each fort of Flower separate, but on the same Plant.

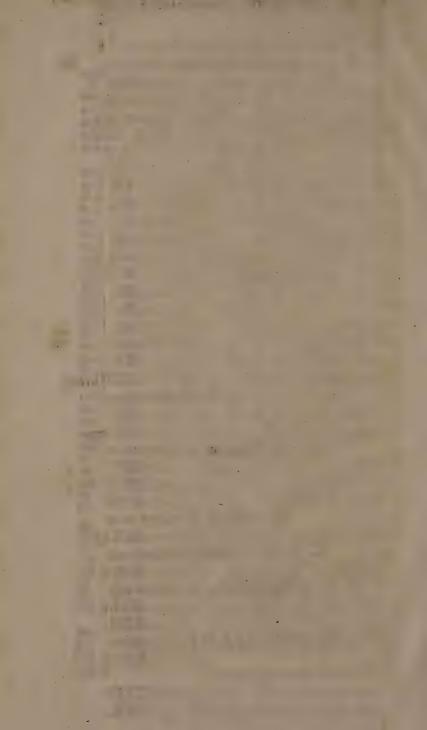

XXII. DIOECIA. Each fort of Flower, on distinct Plants only.

B. 3. Flowers of the first fort, together with one or both of the second sort.

XXIII. POLYGAMIA.

A. Flowers inconspicuous.

XXIV. CRYPTOGOMIA. Flowers very small, invisible, or not yet discovered. XXV. PALMS. Flowers borne on a Spadix, and within a Spathe, mostly incomplete.

## AND SKETCH ORDERS IN THE SYSTEM OF LINNÆUS.

I. Monandria. One stamen.

1. Monogynia. One pistil.

2. Digynia. Two piftils.

II. Diandria. Two stamens.

1. Monogynia. One pistil.

2. Digynia. Two pistils.

3. Trigynia. Three pistils. III. Triandria. Three stamens.

1. Monogynia. One pistil.

2. Digynia. Two piftils.

3. Trigynia. Three pistils.

IV. Tetrandria. Four equal stamens.

I. Monogynia. One pistil.

2. Digynia. Two piftils.

3. Tetragynia. Four pistils.

V. Pentandria. Five stamens.

1. Monogynia. One pistil.

2. Digynia. Two piftils.

3. Trigynia. Three piftils.

4. Tetragynia. Four pistils.

5. Pentagynia. Five pistils.

6. Polygynia. Many pipils.

VI. Hexandria. Six equal stamens.

1. Monogynia. One pistil.

2. Digynia. Two piftits.

Trigynia. Three piftils.

Tetragynia. Four piftils.

5. Polygynia. Many piftils.

VII Heptandria.

VII. Heptandria. Seven stamens.

1. Monogynia. One pistil.

2. Digynia. Two pistils.

3. Tetragynia. Four pistils.

4. Heptagynia. Seven pistils.

VIII. Octandria. Eight stamens.

1. Monogynia. One pistil. 2. Digynia. Two pistils.

3. Trigynia. Three pistils.
4. Tetragynia. Four pistils.

IX. Enneandria. Nine stamens.

1. Monogynia. One pistil.

2. Trigynia. Three pistils.
3. Hexagynia. Six pistils.

X. Decandria. Ten stamens.

1. Monogynia. One pistil.

2. Digynia. Two pistils.

3. Trigynia. Three pistils.

4. Tetragynia. Four pistils. 5. Pentagynia. Five pistils.

6. Decagynia. Ten pistils. XI. Dodecandria. Twelve stamens (from

11 to 19).

1. Monogynia. One pistil.

2. Digynia. Two pistils.

3. Trigynia. Three pistils. 4, Pentagynia. Five pistils.

5. Dodecagynia. Twelve pistils.

XII. Icosandria. Twenty stamens (on the calyx or corolla).

1. Monogynia. One pistil.

2. Digynia. Two pistits.
2. Trigynia. Three pistils.

4. Pentagynia?

4. Pentagynia. Five iffils.

5. Polygynia. Many piftils.

- XIII. Polyandria. Many flamens (from 20 to 1000, on the receptacle).
  - 1. Monogynia. One pistil. 2. Digynia. Two piftels.
  - 3. Trigynia. Three pistils.
  - Tetragynia. Four piftils.
  - 5. Pentagynia. Five pistils.
  - 6. Hexagynia. Six piftils.

7. Polygynia. Many pistils.

- XIV. Didynamia. Four stamens, 2 longer and 2 Shorter.
  - 1. Gymnotpermia. Four naked feeds.
  - 2. Angiotpermia. Seeds inclosed in a pericarp.

XV. Tetradynamia. Six stamens, 4 longer and 2 (horter.

1. Siliculofa. Pericarp generally roundish, with the style permanent or continuing, called a filicle.

2. Siliquosa. Pericarp very long and narrow, called a tilique or pod.

- XVI. Monadelphia. One brotherhood: or filaments all connected.
  - Triandria. I bree stamens.
    - 2. Pentandria. Five stamens.
    - 3. Octandria. Eight slamens.
  - 4. Decandria, Ten stamens.
  - 5. Endecandria. Eleven stamens.
- 6. Dodecandria. Twelve jeamens.
  - 7. Polyandria. Many stamens.
- XVII. Diadelphia. Two brotherhoods: or filaments in two bodies.

T. Pentandria.

- 1. Pentandria. Five stamens.
- 2. Hexandria. Six stamens.
- 3. Octandria. Eight stamens.

4. Decandria Ten stamens.

XVIII. Polyadelphia. Many brotherhoods: filaments in three or more parcels.

1. Pentandria. Five stamens.

- 2. Dodecandria. Twelve stamens.
- 3. Icosandria. Twenty stamens.

4. Polyandria. Many stamens.

XIX. Syngenesia. Congeneration. Anthers united.

1. Polygamia Æqualis. All the flofcules perfect, and the whole flower

regular.

2. Polygamia Superflua. Perfect flofcules in the difk: pistilliferous flofcules in the ray: both producing feed.

3. Polygamia Frustranea. Floscules in the disk perfect, and producing feed: in the ray imperfect, and

without seed.

4. Polygamia Necessaria. Floscules in appearance perfect in the disk, producing no seed: pistilliferous stoscules in the ray producing seed.

5. Polygami Segregata. Many floriferous calyxes contained in one common calyx, and forming one flower.

6. Monogamia. Flowers not compound, as in the other orders, but simple, as in all the other classes.

XX. Gynandria. Stamens growing on the pistil.

1. Diandria.

- 1. Diandria. Two stamens.
- Triandria. Three stamens.
- Tetrandria. Four stamens. Pentandria. Five stamens.
- 5. Hexandria. Six stamens.
- 6. Octandria. Eight stamens.
- 7. Decandria. Ten stamens.
- 8. Dodecandria. Twelve stamens.
- o. Polyandria. Many stamens.

# XXI. Monœcia. One house. Imperfect flowers separate on the same plant.

- 1. Monandria. One stamen.
- 2. Diandria. Two stamens.
- 2. Triandria. Three stamens.
- Tetrandria. Four stamens.
- 5. Pentandria. Five stamens.
- Hexandria. Six stamens.
- 7. Heptandria. Seven stamens.
- 8. Polyandria. Many stamens.
- o. Monadelphia. Filaments united in one.
- 10. Syngenesia. Anthers united.
  11. Gynandria. Stamens on the pistil.

# XXII. Diccia. Two houses. Imperfect flowers on distinct individuals.

- 1. Monandria: One stamen.
- Diandria. Two stamens.
- Triandria. Three stamens.
- Tetrandria. Four stamens.
- 5. Pentandria. Five stamens.
- 6. Hexandria. Six stamens.
- Octandria. Eight stamens.
- 7. Octanoria.

  8. Enneandria. Nine stamens.
- 9. Decandria. Ten stamens.

10. Dodecandria. Twelve stamens.

11. Polyandria. Many stamens.

12. Monadelphia. Filaments united in one.

13. Syngenesia. Anthers united.

14. Gynandria. Stamens on the pistil.

XXIII. Polygamia. Perfect flowers, accompanied with one or both forts of imperfect flowers.

1. Monœcia. Perfect and imperfect

flowers on the same plant.

2. Dioecia. Perfect flowers on one plant,

and imperfect on another.

3. Tricecia. Perfect flowers on one plant, staminiferous flowers on a second, and pistilliferous flowers on a third.

XXIV. Cryptogamia. Fructification fecret.

1. Filices. Ferns: bearing feed on the back of the leaves.

2. Musci. Mosses: having imperfect flowers distinct, and the seeds in a capsule, often covered with a veil.

3. Algæ. Having imperfect flowers distinct, and the seeds either like a meal on the leaves or enclosed in bladders.

4. Fungi. Having no discernible flowers, but seeds in the gills, pores,

cups, &c.

XXV. Palmæ: Palms. Flowers on a spadix, in a spathe or sheath: generally staminiferous and pistilliferous distinct.

LET-

## LETTER XI.

#### OF THE CLASS MONANDRIA.

June the 10th, 1774.

T length, dear cousin, I am going to put you in the way of examining plants by yourself, and determining the genus and species, as you have been already initiated in my first letters; but now I shall proceed in more form, and present you with one plant or more of each class, explaining to you as we go along some others of the natural classes, which form, or are contained in the artificial ones.

The first class, Monandria, in the system of Linnæus is a very small one; comprising, as you have seen already, in the second table which I sent you, but two orders. There are also but eighteen genera in it, and forty-four species. Very sew of these plants are natives of Europe; and the Indian sorts are not easy to be met with, at least in slower, in the best hot-houses.

There is a plant, however, not very un-Hippuris, common in ponds, ditches, and flow muddy streams, called *Hippuris*, which is of this class, and of the first order. It has a single jointed stalk, and at each joint is a dozen

leaves or more, placed all round in a whorl, which is a form that Linnaus calls Verticillate. To each of these leaves, close to the stalk, belongs a little flower, confisting of a fingle stamen and pistil, one feed, and nothing more; for it has neither calyx nor corolla. You will find the stamen sitting on the germ terminated by a bifid anther; and behind this is the style, which is terminated by a stigma tapering to a point. This will be amply sufficient for you to determine the Hippurisi, which perhaps may not grow near you; and if it does, you must not hazard wetting and dirtying yourfelf in a muddy ditch. Since therefore it is abundant in the moat of the neighbouring abbey, I have enclosed some specimens of it in my tin pocket case, which may ferve afterwards to bring home your plants fresh and cool, if you are not already provided with fo necessary a thing. If you are not struck with the beauty of the Hippuris, you will at least esteem it for its modefty and simplicity. I have one favour to ask in return for my tin box and its contents, which is, that, whenever you call this plant by its name, you will pronounce the middle fyllable long, and not short, as

i I do not know that this plant has been noticed enough to have a common name in English. In the books it is called Female Horse-Tail or Mare's Tail. Figured in Curtis, Flora Londinensis. Fascic IV. Plate I. and Plate 7. f. 2. of this work.

many do: for I am folicitous to prenounce, as well as think, like you. I have faid nothing here of the distinction between genus and species, because there is only one more fort of *Hippuris*; and that not much known. I must however inform you, once for all, that we invariably take the characters of the genera from the parts of fructification; and those of the species from the other parts of the plant, particularly the leaves.

There is another plant of this class and Canna,

order, which your gardener may possibly have in the hot-house. I dare say you know it by the upright growth, reedy appearance, and fine scarlet flowers. Perhaps you have already found fome difficulty in determining the class and order; for there is no filament; but the anther grows to the edge of a kind of petal, which Linnæus calls the Nectary: the style also, which is lance-shaped, grows to the same petal. The calyx confifts of three leaves: the corolla is cut into fix parts, five erect, and the fixth reflex; the feeds are contained in a capfule or vessel of three cells, are round and very hard; whence this plant has the name of Indian /bot. Linnæus calls it Canna. Thus much for the genus, of which there are three species at least; some make

\* This is figured by John Miller, in his Illustrations of the Sexual System; by Curtis, in his Magazine, t. 454.—and in Pl. 7. f. 1. of this work.

five. Linnæus has distinguished his three species thus: I. Canna indicak; by its

I

ovate

ovate leaves, sharp-pointed towards both ends, and marked with nerves. 2. C. angustifolia, Narrow-leaved Indian (hot, by its lance-shaped petiolate leaves, marked also with nerves. 3. C. glauca, Sea-green Indian (bot, by its lance-shaped petiolate leaves, Smooth or without nerves! Yours will be one of the two first species, for the last has yellow flowers. This order contains feveral interesting plants, such as ginger. cardamom, grain of paradife, Arabian coftus, turmerick, galangale, &c. all which, with Canna, belong to a natural tribe entitled Scitaminea, from the Latin word scitum, which when tacked to edulium implies eatables of a pleasant or spicy taste. They have not only the same place in the artificial fystem, but they agree farther in having their feeds encloted in a veffel below the receptacle, as you perceive plainly it is in the canna: the divisions also of the calyx, corolla, and feed vessel, are usually three.

Short flights are best, till you have tried your wings. My next may possibly be a little longer, if you give me leave. Adieu for a few days.

<sup>&</sup>lt;sup>1</sup> The Hortus Kewensis has only two species; making Linnæus's second variety only of the first. Willdenow has these three species, and a fourth from China, named Canna Juncea.

# LETTER XII.

### OF THE CLASS DIANDRIA.

June 17th, 1774.

OU have starved a week, dear cousin, upon the meagre fare of my last: I can now promise you more variety, having a larger range and better choice. The second class of plants, diandria, has 35 ge-

nera, and 265 species.

Linnæus has done every thing in his power to facilitate the investigation of plants; and nothing contributes more to this than the clearness and order of his arrangement, and his leading on the student by regular steps from generals to particulars. Thus, after you have fettled the class and order of your plant, you perceive that each order, when numerous, is thrown into feveral great divisions, before you are presented with the generic characters. This shortens your inquiry considerably; for, in the first order of this class, instead of having the characters of thirty-five genera to choose out of, you have by this means only eight or nine, or perhaps no more than three, or even one. That you may understand this the better, I will give IΛ you

you Linnæus's subdivision of the first order of this class.

### DIANDRI MONOGYNIA.

3. Flowers inferior, monopetalous, regular, 8 genera.

lar, with feeds enclosed in a vessel:

o genera.

3. inferior, monopetalous, irregular, with naked feeds: 9 genera.

4. —— inferior, pentapetalous: 1 genus.

5. — fuperior: 3 genera.

So that if your plant happens to belong to the fourth division, it is determined at once: and in all the rest your search is much facilitated.

In this class, though by no means one of the most numerous, you will not be at a loss, either in your garden or in the fields, for examples.

for examples

Jasminum. You are well acquainted with most forts
of jasmine. Take any of them, and you
will perceive immediately that it belongs to
the first division of the first order. Compare as many of the species as you can meet
with in flower, and you will find that they

all agree in the characters of it.

m It is not necessary to be more particular with the English reader, since the Botanical Society at Lichfield have published a translation of Linnæus System of Vegetables.

But

But other circumstances are to be found in them all, called generic characters: these in the present case are: that the corolla is monopetalous, salver-shaped, and the border divided into five segments: the anthers small, and lying within the tube of the corolla: the seed-vessel a berry of two cells: and the seeds covered with an aril or loose coat.

Having seen in what all the jasmines agree, to determine the class, the order with its divisions, and the genus; now attend to the circumstances in which they differ, to settle the six species best known. For this the leaves will nearly suffice, thus:

- 1. Leaves pinnate, opposite: lobes distinct. Jasmine officinal. Curt. Magaz. 31. Pl. 8 s. 2.
- 2. Leaves pinnate, opposite: lobes confluent. J. Catalonian.
- 3. Leaves ternate, opposite. J. Azorian.
  - 4. Leaves ternate and simple, alternate: branches angular: J. shrubby. Curt. Magaz. 461.
  - 5. Leaves ternate and pinnate, alternate, acute: branches angular. J. dwarf.
  - obtuse: branches round. J. fweetfcented. Curt. Magaz. 285.

The

n If the reader be at a loss for the meaning of terms, there is no want of books to confult; such as Lee's and Rose's Introductions, Martyn's Language of Botany, &c.

The three first have the corolla white: in the three last it is yellow. If you inquire after your favourite Arabian jasmine, it belongs to another genus, Ny Etanthes, because it has the calyx and corolla divided into eight fegments. The Cape jasmine is of another class, the fifth; and of course has

another name, Gardenia.

Several other trees and shrubs belong to this same first division. Privet, Phillyrea, Olive, and the Lilacs. These have all a quadrifid corolla, and are distinguished by their fruit, which in privet is a berry with four feeds; in phillyrea a berry with one feed; in olive a drupe; in the lilacs a bilocular capsule. The common lilac has heart-shaped leaves; a circumstance sufficient to distinguish it from the Persian, which has lance-shaped leaves. As to the different colours of the flowers in the first-white, blue, and red—they form but varieties; colour being rarely permanent enough to constitute specific differences.

Veronica In the second division is a genus, named, from a female faint, Veronica: it is a very numerous one, containing no less than forty species. Here therefore Linnæus has done with the genus, as he did before with the order—he has thrown it into three principal divisions from the manner of flowering. 1. Such as bear the flowers in spikes. 2. Such as bear them in racemes or bunches. 3. Such as produce them fingly.

This genus is easily known by the monopetalous, rotate, or wheel-shaped corolla, divided into four segments, the lowest of which is narrower than the rest; and the bilocular, heart-shaped, flatted capsule.

One species is very common among buthes, and in the edges of pastures. Its beautiful blue flowers have doubtless attracted your notice, and, in falling off too easily, have given occasion perhaps to a lesson on the short duration of our enjoyments, or the fleeting nature of female charms, to your lovely daughter. If it be not already past flowering, for May is its feafon, you will find that it belongs to the fecond division; or even if it be, the oval, wrinkled leaves, indented about the edge. and fitting close to the stalk together with the weak trailing items, unless upheld by the bushes, will so clearly point out this humble plant to you, that you cannot well be mistaken .

If this species, however, is out of blow, you will certainly find another in dry pastures or heaths, especially upon old anthills: it may perhaps have escaped you, the flowers being small and of a pale colour: not however without their beauty, on a nearer survey. This belongs to the

P Veronica officinalis. Officinal Speedwell, Curtis,

Lond. III. 1,

<sup>Veronica Chamædrys. Wild Speedwell or Germander, Curtis, Lond. 1. 2.—Pl. 8. f. 1. Fl. Ruft. t.
66. English Bot. 623.</sup> 

first division, having the flowers growing in spikes, coming out chiefly from the side of the plants, at some distance from the main stem; the leaves are opposite, and the stalks trail along the ground. It has the trivial name of officinal, because an insusion of it is sometimes used medicinally.

Other species are common by the sides of ditches and brooks, whence they have the name of Water Speedwell, or Brooklime<sup>4</sup>: these are of the second division: and three species of the third division are abundant

among corn in the fpring'.

I know not how it is, but there is a connexion between this class and the fourteenth. Pinguicula or Butterwort has a personate flower. Some species of Vervain have two stamens, others four of unequal lengths; among the latter is our common or officinal Vervain's: whence fome authors have removed it to the class didynamia. Sage, Rosemary, and others, have labiate flowers. and in every respect so resemble the plants of the fourteenth class, that they should naturally be placed there; but having only two stamens, the artificial system ranges them in this class. Sage seems to form the connecting link between the two classes; for in this genus are rudiments of

o Curtis, Lond. I. 41.

Salvia.

Veronica Becabunga, Curtis, Lond. II. 3. Engl. Bot. 655. is one of these.

Veronica arventis: Curtis, Lond. II. 2. agrestis: Curtis, Lond. I. 1. hederifolia: Curtis, Lond. II. 1.

another pair of stamens, but without anthers. The structure of the stamens in the sage is singular, and merits your observation. The two silaments are very short, but two others are sastened to these transversely by the middle; and at one end of these last is a gland, at the other an anther. This circumstance distinguishes the genus from all others, and is called its essential character. If you compare the slowers of sage and rosemary together, you will find them agree in most other particulars; but rosemary has not this character: it has very long silaments, bending towards the casque or upper lip of the corolla.

The genus Salvia or Sage has no less than fifty-two species. Our common garden sage, of which there are several varieties, has the flowers growing in spikes, the segments of the calyx acute, and the leaves of an oblong ovate form, entire and very slightly notched about the edges. There are two forts commonly wild in Europe, not very unlike each other, but rather clarys than sages: you will be at no loss to know them when you see them. To distinguish them from each other, observe that Meadow Clary, has the leaves oblong-hearts shaped, and notched about the edges; the

<sup>&</sup>lt;sup>2</sup> Salvia officinalis *Linnæi*. Pl. 8. f.3. Ger. 764.

<sup>3</sup> Salvia pretenfis & verbenaca; but the latter only se common in England.

ers grow in almost naked whorls, and the upper lip of the corolla is glutinous. The Wild Clary\* has the leaf ferrate, sinuate, and smoothish: the tube of the corolla very small in comparison with the calyx, which opens wide.

But enough for our fecond excursion, especially as I propose that we should take

a third very foon.

\*\* Salvia verbenaca. Engl. Bot. t. 154. Ger. 771. 1. The edition of Gerald's Herbal, which is quoted here and elfewhere, is that which received the additions of Johnson, and was printed in 1663.

## LETTER XIII.

OF CORN AND GRASSES.

June the 24th, 1774.

HAVE hastened this letter, dear coufin, lest the industrious mower should have spoiled our harvest. The brilliancy of the present season will perhaps have quickened his steps: but at the worst, he will have left you some gleanings about the

hedges.

The tribe which I now recommend to your examination is the most known and general of any; it is the most pleasant to the eye, and of the most extended use since it furnishes man with the best portion of his nourishment, and at the same time is the whole support of many among the beasts, and of a large proportion of birds. The most rigid critic cannot accuse us of mispending our time, when we are engaged in the contemplation of so useful a tribe of plants as that which contains all the different species of corn and grasses.

The former being larger, requiring more care and culture, because they are annual, and being immediately necessary to the support of man, and the animals about him, in this and many other countries; the species

are univerfally known and diftinguished. But this is not the case in the latter; grass vulgarly forms one single idea; and a husbandman, when he is looking over his inclosure, does not dream that there are upwards of three hundred species of grass, of which thirty or forty may be at present under his eye. They have scarcely had a name, besides the general one, till within these twenty years; and the sew particular names that have been lately given are far from having obtained general use; so that we may fairly affert that the knowledge of this most common and valuable tribe of plants is yet in its infancy.

Let us not, however, give more importance to botany than it really has; but proceed quietly with our own business. The greater part of the world scarcely know that grass has a flower; or, if they are shown

<sup>\*</sup> The late excellent Mr. Stillingfleet first directed the public attention to graffes; and that most respectable and useful institution, the Society of Arts, &c. has done all in its power to promote an improvement in the culture of them; but without great effect. Nor can much be expected till economical gardens or public farms are instituted, for the purpose of experiments in this and other parts of husbandry. It is not enough to tell men of a good thing, and instruct them how it may be done; but they must actually see it put in execution, and be eye-witnesses of its good effects. This has lately been done by some public-spirited gentlemen; particularly by Mr. Coke, of Norfolk. See Young's Annals .- Mr. Curtis's Practical Observations on the British Grasses are highly deferving of the attention of the public. - See also Mr. Swayne's Gramina Pascua. it.

it, will coldly ask, Is this all? And yet grass not only has a flower, but every constituent part of it; which is more than we can say of a tulip, and some others, that have engrossed almost all the attention of mankind: nay, there is such a variety in the parts, disposition, and manner of flowering, that we have sufficient marks in the fructification to distinguish above forty genera.

If you take up a spikey or panicle of grass, you may perhaps be disappointed in your expectation of discerning the stamens and other parts; be affured then that the flower is not yet open, and continue your fearch till you find one with the parts expanded, the slender filaments hanging out, and large, oblong, double anthers playing freely about with the flightest motion. You will immediately perceive that your grass. having three of these stamens, must range under the third class, triandria, provided the flower has a pistil as well as stamens. Searching a little farther, you will eafily detect two reflex styles, each terminated with a feathered stigma: you are at no loss, therefore, to determine that your grass belongs to the second order (digynia) of this third class\*.

Having thus fettled the class and the order, you will proceed to the other parts of

y Pl. 9. f. 1. Pl. 9. f. 2. See Pl. 9. b, c.

K

the flower. The neglected chaff you will find to be double: the outer generally confifting of two leaflets, one large and gibbous. the other smaller and flat; the inner confifting also of two parts or valves, which you may call petals, for this is the corolla, and the former is the calyx. Nay this despised flower has even its nectary; which is a little oblong body composed of two leaflets, but fo fmall as to require a glass to discern it well. Graffes have no pericarp, but one naked feed, with the shape of which we are well acquainted—it is oblong, and draws to a point towards each end. These characters you will find common to every grass you examine, and also to every species of corn: or, however, with very few exceptions: this then is called the classical character. As these fmall flowers grow frequently two or more close together, you have only to separate a fingle flower to avoid confusion in your examination.

But this tribe of plants does not agree in the parts of fructification only, as above deferibed. The whole appearance, the general air, the manner of growth, is the fame in all. A simplicity of structure runs through the entire class. Every one has a simple, unbranched, straight, hollow stem, strengthened with knots at certain intervals. There is none but has a single leaf to

each knot, investing or sheathing the stem to some distance, and then spreading out into a long narrow furface, of equal breadth - all the way till it approaches the end, when it draws off gradually to a point. It is also invariably entire in every species, and without veins or branching veffels, being only marked longitudinally with lines parallel to the fides, and to a nerve or ridge that runs the whole length of it. There is another eurious circumstance, almost peculiar to this tribe of plants, and common to them all: namely, that the body of the feed does not fplit into two lobes, but continues entired. till it has accomplished its purpose of giving the young plant its first nourishment, and then rots away. This you may eafily obferve as corn is fpringing up; or you may fow a little Canary grass-feed, which you have for your birds, in a garden-pot in your window, and thus make the observation at home. But, though I may indulge you for once, you know I do not encourage this idle domestic manner of observing the operations of Nature. You must go abroad and view her feated on her native throne: and in her court you have this advantage, which you will find in no other, that you are gathering health whilst you pay her homage.

Linnæus calls this fort of leaf linear.

d Such plants are called monocotyledonous; the others, dicotyledonous.

If you are now mistress of all the circumstances in which this tribe of plants agree, you may proceed to those in which they differ, and thus separate them first into their genera, and then into their species. But, the genera being numerous, it may not be inconvenient, as we did once before, to throw the whole tribe into some general fubdivisions; and that we can easily do from the manner in which the flowers are produced-either in a panicle or spike; and fingly, or feveral together. Hence we shall get four subdivisions.

1. Flowers fingle -2. Flowers two together - 2 genera.

2. Flowers many together - 7 genera. These are mostly panicled: in all, the flowers are irregularly disposed, or wan-

dering, as Linnæus calls them.

4. Flowers in a spike, with a subulate receptacle Including wheat, rye, and barley. Oat is in the third division.

Phalaris. Your pot of Canary-feed, if you do not pull up all the plants to verify what I told you before, will serve for an instance of the first division. When it arrives at a state of perfection, you will observe that the two leaves of the calyx are flatted, boat-shaped, have a keel running along them, and are equal in length; the corolla is lefs than the calyx, calyx, and shut up within it. This is the character of the genus. It is specifically distinguished by the form of the panicle resembling a spike and being ovate, the chass being turgid and hairy, but the keel smooth. It is an annual grass, is found wild in the Canary Islands, whence its name of *Phalaris canariens*, and is cultivated in Europe for the food of Canary and other small birds.

Whilst your Canary-grass is growing, you must go out in search of other instances of this first division; for I must absolutely insist that you ransack the neighbouring meadows and pastures before the furious

fcythe has levelled all their honours.

Meadows of a good quality abound in Alopecu-Fox-tail grass, which is indeed one of therus. earliest, as well as the most excellent, for hay and feeding cattle. This genus is an exception to one of the general characters; for, though the calyx has two valves or leaves, the corolla has but one. You will readily discover the species by the cylindric shape and hoary appearance of the panicle, which, from its form, you will take for a spike, the erectness of the stalk, and the corollas not being bearded.

Cat's-tail grafs is another of these; the Phleum. spike has not the smooth hoary appearance of the last, but seems rough, and is known

K 2

Alopecurus pratenfis Linnæi. Stillingfl. t. 9. Curtis, Lond. 5. 5. & obs. t. 2. Fl. Rust. t. 6.
Phleum pratense. Lin. Schreber, t. 14. Fl. Rust. t. 5.

at first fight by the truncated and forked termination of the calyxes, which are also linear, and fit close to the stem. The corolla is shut up within the calvx. The shape of the spike is cylindric, the keel of the chaffs is ciliateg, and the stalk is erect. The spike of cat's-tail grass is sometimes four inches long in moist meadows; in drier, poorer foils it decreases in length, until it dwindles to half an inch; and even less in hard barren ground, fuch as wayfides and heaths. In these last it connot raife itself upright; and the roots not being able to spread themselves freely, grow knotty and bulbous. I mention there circumstances, that you may be aware of the changes wrought in plants by foil and fituation, and not suppose that a new species presents itself every time you meet with these and other flight variations. If you transplant from the heath into your garden a dwarf, crooked, knobby-rooted plant, I dare engage that the stem will become erect, that the spike will lengthen, and the bulbous root change to a fibrous one. It is not, however, always easy to say what is a species, and what a variety only. A great deal of observation and experience is necessary in many cases to determine this with precision. Most varieties indeed are produced by culture, or a change from their

<sup>2</sup> Set with little hairs like eye-lashes.

native foil and situation; and, when they regain their natural state, will return to their prissine form: if this were universally so, there would be no difficulty to ascertain the species from the variety. But it sometimes happens that, when accident has produced a variety, it continues permanent; and, having once tasted a polished situation, resules to return to a state of nature. Our test therefore is not a certain one.

The second division of the grasses having only two genera, the distinction is easy: they are known from the rest by having two flowers growing together; and from each other by the rudiment of a third flower between the two others in the Melica, of which there is no sign in the Aira.

Of the third division you will find abundance of grasses sufficiently common; Briza or ladies' hair, Poa or meadow-grass, Festuca or sescue, Brome grass, oats with all the oat-grasses, and the reeds. The genera are

thus distinguished:

Corolla cordate: valves turgid, - Briza.

Corolla ovate: valves rather tharp, Poa.

Corolla oblong: valves pointed, - Festuca.

i valves bearded below the point, - Bromus.

beard writhed or bent, - Avena.

Corolla woolly at the base: awnless, - - Arundo.

K 4

Briza.

The Brizas, of which there are five forts, are very pretty graffes; infomuch that one of them is cultivated in gardens for its beauty and fingular appearance. They flower early in the month of May, grow in a loose panicle, the foot-stalks of which are so slender as to be moved by every wind; whence they have obtained the name of Quaking-graffes. By these circumstances, and their general air different from their other neighbours, you cannot fail of knowing them. The three forts which you are likely to meet with are thus distinguished:

1. Spiculesh triangular: calyx longer than the flower. Little Briza. Mor. 8.

6. 47.

2. Spicules ovate: calyx shorter than the flower, Middle Briza. Mor. 45. Ger. 36. 2. Fl. Ruft. t. 39. Engl. Bot. 340.

3. Spicules cordate: 17 flowers. Great Briza. Jacq. Obs. 3. 60. Curt. Magaz. 357.

The fecond is the fort which is common in meadows, and the third is that which is cultivated in gardens: in this the flowers grow in a raceme rather than a panicle.

Pos.

The Meadow-graffes are numerous, there being no less than 33 sorts registered by Linnæus, and feveral of them are thrown abundantly from the lap of nature; for

perhaps

h These are the little assemblages of slowers, or ultimate subdivisions of the panicle or whole.

perhaps they are the best of all the grasses for pastures, the quantity of their produce being very great, their quality excellent both for green and dry food, and their verdure most fresh and pleasant. But we are not husbandmen, dear cousin; Botany is our

pursuit.

There are four forts of Poa very common in most meadows, which I shall distinguish by the names of 1. Great; 2. Trivial; 3. Narrow leaved; and 4. Annual. They all flower in a loofe branching panicle. The stalks of the first fort are generally erect, and throw out runners: the leaves are rather blunt at the end, and the membrane at the bottom is short and blunt: the spicules are ovate, and on short foot-stalks; the flowers growing close together, most commonly five in number. Every part of this grass is smooth. The second fort is distinguished by the leaves being sharper at the end, and having the membrane at bottom long and pointed: the spicules consist of two or three flowers, very feldom four. The whole of this species is rough. The third has the stems more erect: the leaves sharp-pointed and roughish, but smooth where they sheathe the stalk: the panicle is more erect than the others; the spicules

<sup>1.</sup> Curtis, Lond. II. 5. observ. t. 3. 2. Curtis, Lond. II. 6. observ. t. 4.

<sup>3.</sup> Morison's Hist. s. 8. t. 5. f. 19.

<sup>4.</sup> Curtis, Lond. I. 6. Stillingfl. t. 7. Fl. Ruft. t. 98.

on longer foot-stalks, with from one to six showers, which are hairy at the base. These three are perennial. The fourth is annual, and smaller than the others; extremely universal, and in flower the greatest part of the year; it has a very loose spreading panicle growing all on one side, the lower branches of it often coming out in pairs: the spicules producing three or four flowers: the stalk

is oblique and compressed.

I must give you one caution in examining these and the rest of the panicled grasses, which is this-that you should take them at the time when they are arrived at full maturity; that is, when the panicle is completely expanded, and the flowers show their stamens: for, at different periods of their existence, these grasses put on such various appearances, that they have deceived many eminent Botanists into forming several species out of one. To have the history of a plant complete, we ought to examine it every day during the whole time of its growth. What a work would fuch a history of ten thousand plants form! But the book of nature is inexhaustible.

Festuca.

The genus Festuca or Fescue grass, though less numerous than the last, yet contains 19 species. Sheep's fescuek is a well known grass, always to be found in dry pastures,

i This is what Linnæus calls Panicula secunda.

<sup>1</sup> Festuca ovina. Stillings, t. 8. English Bot. 585. Fl. Rust, 102.

and sheep-commons. It has a close contracted panicle, growing on one side; the spicules having from three to six slowers; the valves of the slowers are very sharp-pointed, but seldom properly awned; the culm is rather square than round, almost naked, and the leaves are setaceous.

Another fescuem, extremely different from the former, grows in watery places, ponds, and ditches. It has a loofe panicle of a confiderable length, but little branching, growing on one fide; the branches of the panicle are fometimes fingle and fometimes double; the spicules are round, linear, and awnless, almost an inch long, and pressed close to the stalk; varying in the number of flowers from 9 to 12. The leaves are not round like those of the last. but flat; and the culm is very long, procumbent, branching and flatted. The feeds of this being large and sweetish are gathered for the table in Poland and some other countries, and appear there under the name of Manna.

Meadow Fescue, one of the best grasses for cultivation, has a culm two feet high, leaves rough to the touch, large loose panicles, the spicules acuminate, smooth, varying in the number of slowers from fix to eight. It is found in a variety of soils,

<sup>. 1</sup> Very narrow, like those of rushes.

m Festuca stuitans; store Fescue. Curtis, Lond. I. 7. Fl. Rust. 113.

from the fand-pit to the ofier-holt "Tall Fescue", which much resembles it, is twice the height, the leaves are twice as broad, the panicle is longer, contains double the number of flowers, branches twice, droops greatly at first, the flowers grow much more loosely, and the spicules are somewhat flat, linear, and blunt.

Bromus.

The Bromes are very nearly allied to the Fescues. They are distinguished, however, by being all bearded, and the beard or awn springing from the back, or below the tip of the chaff: whereas the Fescues are often beardless; and when the flowers have a beard, it is an elongation of the chaff itself.

No grass is more common in many pastures than Field Brome grass. It has a loose unbranched panicle: the spicules are ovate, the slowers are obtuse, and the beards are straight. It is an annual plant, and varies so much as to have obtained the name of polymorphus or many formed. The two principal varieties are, I. That which has a soft down all over the panicles, leaves, and stalks, with larger, heavier spicules:—2. That which is smooth all over, with the spicules thinner, and not hanging down so

much,

<sup>&</sup>lt;sup>n</sup> Festuca pratensis. Curt. obs. t. 5. Fl. Rust. t. 84.

<sup>·</sup> Festuca elatior.

p Bromus mollis & fecalinus Linnæi. Mr. Hudson, after Scopoli, has very judiciously made them one, under the title polymorphus. Curtis, Lond. I. 8. figures the mollis—Morison figures this in t. 7. f. 18; and secalinus in f. 16.

much, but often rather erect. Between these are two other varieties: 1. With the leaves downy, and the panicle almost smooth: 2. With the lower leaves only a little downy. and the panicle quite smooth. Other connecting links may eafily be remarked by those who are industrious in hunting after varieties.

There are three very large species of this genus, to be met with in woods and hedges. but feldom in pastures9. They have great. branching, nodding panicles. Barren Brome is not very tall; but the Giant and Wood Bromes are three feet in height. Their fize, added to the character and air of the genus. mark them out fo well, that you will not

easily mistake when you see them.

You will get an idea of the Oat graffes Aven. from the corn of that name, which, having the parts of fructification larger than in the graffes, gives you an advantage in the examination. Bearded Oat grass, vulgarly called Wild Oats, is also well known as a dreadful weed among corn. Yellow Oat grass is common in meadows and pastures: it is a neat pretty grass, and will discover of its panicle. 1980 9 and pellowness

The characters of the above-mentioned species are these:

1. Two flowers in one calyx: the feeds

Imouth.

<sup>9</sup> Bromus sterilis, Curtis I. 9. & Fl. Ruft. 125. giganteus, Curt. 5. 7. & nemoralis, Fl. Ruft. 126.

fmooth, and one of them bearded. Cultivated Oats.

2. Three flowers in one calyx: hairy at the base, and all of them bearded. Wild Oats.

3. Panicle loose: three flowers in a short calyx, and all of them bearded. Yel-

low Oat grafs.

Arundo. The woollyness of the flowers in the Reed will shew you this genus as foon as it unfolds its panicle. It is a grafs, though vulgarly not regarded as fuch, because it is not used for the same purposes with the graffes. That, however, makes no difference to us, whose province it is not to regard the uses to which plants are put, but their structure. If husbandmen will not admit reed to be a grass, they take in other plants to their idea of grass which we exclude, such as clover, lucerne, faintfoin, &c. The reason is, that they consider grass as an herb adapted to feed cattle: whereas naturalists define it to be an herb which has generally three stamens and two pistils, always an unbranched, knotted, hollow stem, and simple linear leaves.

Though you are perfectly acquainted with the reed', it is perhaps rather by feeing it nodding its large panicles in the water at a distance, or else by the use which

8 Arundo phragmites Linnai. Morif. 8. 8. 1. Engl.

Bot. 401.

Avena fativa, fatua, & flavescen. Linnæi. Fl. Rust. t. 79, 81, 112. and Curtis, Lond. III, 5.

your gardener makes of the long light stems for hedges to guard his tender plants, than by its fructification. You will not therefore be displeased to be told that it is distinguished from the other species, which are six, by the looseness of its panicle, and by having sive slowers growing together.

You are now arrived at the last division of corn and grasses, containing those whose fructification is always in a spike properly

fo called. Of thefe,

Secal or Rie, has two flowers included in the fame calyx.

Triticum or Wheat, has several flowers in

one calyx.

Hordeum or Barley, has a fix-leaved involucre, containing three flowers; and the flowers simple.

Lolium or Darnel, has a one-leaved involucre, containing one flower only; but

that flower compound.

Cynosorus or Dog's-tail grass, has a oneleaved lateral involucre, and a compound flower.

In Rie the exterior valve or chaff of the Secale corolla ends in a long beard or awn. The flowers are feffile; and there is frequently a third between these which is less and pedunculate: the filaments hang out of the flower. Our cultivated species is known by the rough hairs upon the chaff.

Hordeum In Barley also the exterior valve of the corolla ends in a long awn. The flowers are sessible. The filaments, being shorter than the corolla, do not hang out; and therefore Barley is not liable to be damaged by rain as rie and wheat.

There are four forts of Barley.

1. The common, distinguished by its two rows of erect beards; all the flowers being

perfect and bearded.

2. The long-eared, having the grains regularly ranged in a long double row, lying close over each other; and flowers on the fides without pistils or beards.—These two species have the chaff very thin.

3. Sprat Barley, with shorter, broader ears, longer beards, the grains placed closer, and the straw shorter and coarser. This also has impersect slowers on the sides of

the ear.

4. Winter or Square Barley, very distinct by having fix rows of grains equally ranged, all furnished with awns, and perfect. The grain of this is large.

Besides these species of corn, the genus contains several grasses. Wall Barley grass is very common by way sides, and under

1. Hordeum vulgare. Fl. Rust. t. 90.

2. Hordeum zeocriton. 3. Hordeum distichon.

4. Hordeum hexastichon; called also bear and big. Fl. Rust. t. 107.

"Hordeum murinum Linnæi. Curt. Lond. 5. 9. Fl. Dan. t. 629. Mor. hift. t. 6. f. 4. Fl. Ruft. t. 43.

walls: and Meadow Barley grass, which is very like it, only that it has a longer stalk and a shorter spike, is found in moist meadows. The common name of this last is rie-grass; and indeed it refembles rie more than barley. I have feen it cultivated alone; but the fort which is generally fown, and vulgarly called rie-grass, is in reality Raygrass, which will be announced to you prefently. These two forts, though apparently so alike, and thought to be but varieties by many, are however very distinguishable: the wall barley-grass having the imperfect lateral flowers bearded, and the intermediate involucres ciliate; whereas the meadow barley-grass has the same flowers beardless. and the involucres very narrow, like briftles. and rough.

In Wheat the exterior valve of the co-Triticum rolla is fometimes bearded, but not always. There are generally three or four flowers in the fame calyx, and the middle one is frequently imperfect. The filaments hang out,

but not fo much as in rie.

1. Common Wheat has four flowers in one calyx; the chaffs are smooth, turgid, imbricate; sometimes it has short beards, but more often none: hence and from the colour, &c. are several varieties which husbandmen notice, and we have nothing to do with.

v Hordeum pratense. Fl. Dan. t. 630. Mor. Hist. t. 2. f. 6. Fl. Rust. t. 108. Engl. Bot. 409.

2. Summer or Spring Wheat has also four flowers together, and agrees with the former in the other characters, except that it.

is always bearded.

3. Gray Wheat has villous, turgid, imbricate obtuse chaffs, containing sour flowers. The ears are large, heavy, and nodding; the beards are very long, and drop off when the grain is full grown: the chaff being villous all over gives the ear a gray appearance.

4. Cone Wheat has villous, turgid, imbricate chaffs, and the ear of a pyramidal form ending in a flender point: the beards

are long and rough.

5. Polonian Wheat has two flowers only in each calyx, naked, and having very long awns; with the teeth of the rachis or receptacle of the spike bearded. The ears are

long and heavy,

6. Spelt has four flowers, but two only produce any grain; the outer ones are abortive, as the lower ones are in every ear: the outer chaff of the perfect flowers has a beard about an inch long. The flowers are more conical, and the grain is less than in wheat: the chaff also is adherent.

2. Triticum æstivum.

<sup>3.</sup> Triticum turgidum: called also Gray Pollard, Duck-bill, and Fuller's Wheat.

<sup>4.</sup> Not noticed by Linnæus. 5. Triticum Polonicum.

<sup>6.</sup> Triticum Spelta. I do not know that this fort is ever cultivated in England.

Few plants are more universal than one grafs of this genus; it is known by the name of Dogs grass, and generally execrated by husbandmen under the name of Couch, or Quich, which is but a corruption of Quick, the ancient term for living. It well deserves this appellation, for it runs prodigiously at the root, and, like Hercules's hydra, the more you hack and cut it, the faster it propagates itself. It is distinguished from the several species of corn by the smallness of the ear and the grain, and also in the being perennial; whereas all forts of corn are annual: from the other graffes of the same genus, by having many flowers,. about five generally to one calyx, and those not bearded, but very sharp-pointed at the endw. There is another species, which has about four flowers in a calyx and is bearded\*. This grows in woods and hedges.

Before I quit this genus I must observe, as a singularity, that it is not known, with any degree of certainty, to what country we are originally indebted for the several species of corn, or whether they now grow wild in any. One says that wheat came first from Africa; others, with more probability, that it travelled into Europe from

w Triticum repens Linnai. Schreb. t. 26. Fl. Dan. 748. Mor. Hift. t. 1. f. 8. Fl. Ruft. 124. The number of flowers varies from 2 to 8. Hudfon.

ber of flowers varies from 3 to 8. Hudson.

L 2 the

the East. Linnæus affirms that rie grows naturally in Crete<sup>y</sup>; and spring wheat, with sprat barley (Hordeum distriction), in Tartary: but upon what authority I know not. A late traveller also found barley and oats in Sicily, growing like weeds among the bushes; but he does not pretend to determine whether they grew there originally wild, or whether they were stragglers from the fields where they had been cultivated <sup>z</sup>.

Lolium. Lolium or Darnel-grass is an exception to the general character; for it has only one chaff or leaf to the calyx. The reason of this is, that the spicules are sessile, and in the same plane with the culm, which by this position is enabled to perform the office of the desicient leaf of the calyx in protecting the seed. This single chaff contains several flowers. Of the two common species

y It is faid also to be wild in Siberia.

<sup>&</sup>lt;sup>2</sup> Voyage en Sicile, &c. Lausanne, 1773. Diodorus Siculus, from the report of others, and Pliny, affert that grain grew in the Leontine fields, and other parts of Sicily, spontaneously: but this was only during the reign of Ceres. Aristotle also says (de Mirabil. Auscult.), that there is a wild wheat in the neighbourhood of Mount Ætna. The passage in Homer's Odyssey is well known:

<sup>&</sup>quot;The foil untill'd a ready harvest yields,
"With Wheat and Barley wave the golden fields."

Wheat, barley, yetches, fesame, &c. are said by Berosus to be wild in Babylonia, between the Tigris and Euphrates.

in this genus one is perennial2, the other annualb. The first is found naturally in meadows, pastures, and by way-fides. The distinctive marks of the species are, that the spicules in the first are longer than the calyx, and the flowers beardless: whereas in the fecond, which is a weed among the corn, the spicules are only of equal length with the calyx, and the flowers have short beards. Sometimes however it happens that the flowers of the perennial fort have little beards, and those of the annual none: but you may always know them, not only from their duration and place of growth, but because the second is larger in every respect; the stalk higher, the spike longer; the spicules also are much more remote, so that they do not touch each other, as they do in the first.

Cynosurus, or Dog's-tail grass, was the Cynosulast mentioned of this division. The charus. racter of the genus is taken from a lateral leaf to each calyx, which Linnæus calls the receptacle, involucre or bracte: this gives

b Lolium temulentum Linnæi. Schreb. t. 36, Fl.

Dan. 160. Fl. Rust. t. 33.

<sup>&</sup>lt;sup>a</sup> Lolium perenne Linnai. Schreb. t. 37. Fl. Dan. 747. Mor. Hist. t. 2. f. 2. Pl. 9. f. 1. Engl. Bot. 315. and Flora Rustica, t. 4. This is the fort which has been long cuitivated in England under the name of Rie-grass, which is a corruption of Ray-grass; and that is derived from the French Yvray, a name given to the second sort, from its quality of affecting the nerves, something like drunkenness: which makes it to be reputed a dangerous weed among wheat.

the spike an air by which the genus is easily known from all others. There is an elegant species, very general in parks and on commons, and found also in other pastures, which has these bractes pinnatisid, or toothed like a comb: the corolla does not open, but closely invests the seed, which therefore does not fall; the spicules have from three to sive slowers, are all turned the same way, and do not sit close to the receptacle or common stalk of the spike; one peduncle supports sometimes two or three of these spicules. The stalk is very erect and slim, and the leaves are narrow and smooth.

There remain still some grasses which militate against the artificial system, and are therefore not to be found in the third class of Linnæus's. But as we are not bound to follow him servilely, we will rather follow

nature, a better guide.

Anthoxanthum. Earlier than most of the rest slowers a grass, called from thence Vernal Grass. Linnæus has named it Anthoxanthum, from the yellowness of its spike. This will serve at present to introduce it to your acquaintance, until you have an opportunity next spring to examine the slowers more minutely. It has obtained the epithet of

d Curtis, Lond. I. 4. and observ. t. 1. Stillingsleet,

t. r. Fl. Ruft. t. 23. Engl. Bot. 647.

odoratum

Cynofurus criftatus Lin. Crefted Dog's-tail. Schreb. t. 8. f. 1. Stillingfleet, t. 11. Curtis obf. t. 6. Engl. Bot. 316. Fl. Ruft. 106.

odoratum from the fweet odour which it communicates to hay. This genus stands alone in the fecond order of the fecond class. Each calyx sustains but one flower: each valve of the corolla has an awn, one bent, and proceeding from the bafe, the other almost from the top: the two filaments are very long; and the two styles are filiform: the chaff of the corolla adheres to the feed. There are three species of the genus: ours is distinguished by the spike being of an oblong form, and the flowers growing on short peduncles, and being longer than the beards. We said he w

There is also one species of grass, called Cinna, in the second order of the first class.

But in the first order of the twenty- Holcus. third classe are several genera; of which the Holcus or Soft grass is most likely to come under your observation. This, and all the others, have smaller imperfect flowers among the perfect ones; a circumstance which constitutes them of that class. They have all bivalvular chaffs for calyx and corolla; three stamens, two pistils, and one feed, together with the whole port or air of the plants we have been just confidering: circumstances which plainly denominate them grasses. Holcus differs from its neighbours, in having two flowers inclosed in one calyx, which is beardless; whereas the

e Polygamia Minœcia.

L 4

outer

outer valve of the corolla generally has a beard. The imperfect flowers have neither corolla, piftil, nor feed, but only three stamens within the bivalvular chaff of the calvx. The two common wild species are thus distinguished: Meadow Soft grass has villous chaffs: the perfect flowers are beardless; the imperfect have a bent awn. Creeping soft grass has smoothish chaffs: the perfect flowers are beardless, but the imperfect have a jointed awn. They are very much alike; but the calyx is more acute in this than in the former, or indeed than in any of the species. The first grows in pastures; the second in corn-fields and hedges.

Since it is not uncommon to find incomplete or imperfect flowers among those which are perfect, in many of the grasses which are ranged by Linnæus in his third class, you will perhaps ask me why he has not either put them also in the twenty-third, or else ranged them all together in the third. To this question I cannot return you a better answer, than that the imperfect flowers seem not so constant and regular in the one as in the other; or perhaps are to be met with only in one species

of the genus.

f Holcus lanatus Lin. Curtis, Lond. IV. 11. Schreber, t. 20. f. 1. Fl. Ruft. 118.

<sup>&</sup>lt;sup>8</sup> Holcus mollis Lin. Curtis, Lond. V. 8. Schreber, t. 20. f. 2. Fl. Rust. 119.

We have now run through the graffes; there are many other plants very nearly allied to them; as Schænus or Bog-rush, Cyperus, Scirpus, Club-rush or Bulrush, all three very numerous genera, Eriophorum or Cotton grassi, &c. in the first order of the third class. Cat's-tailk, Bur-reedl, and all the Carices or Sedges", in the third order of the twenty-first. These have the manner of growth, the leaves, the appearance of grass; they have also three stamens: but the stalk is filled with a spongy substance, and the flower is destitute of petals. Finally, the rulbes and some few others, in the first order of the fixth class, have a fix-leaved calyx, a hexapetalous corolla, or none, fix stamens, and the feeds in a triangular capsule.

I have not told you all this while that Sugar is a grass of the first division, which perhaps you did not expect. But if you are not tired, dear cousin, I am; so adieu for the present.

## LETTER XIV.

OF OTHER PLANTS IN THE CLASS
TRIANDRIA. A 19

July the 1st, 1774.

You are not to suppose that, because the last letter was engrossed wholly by grasses, the third class, therefore, of the system contains no other plants. In truth there are no fewer than seventy-six genera, and six hundred and eighteen species, in the three orders of this class taken together. You see however, that, though the grasses do not occupy the whole, they make a very large

proportion of it.

There are some very beautiful genera in the first order of this class, particularly the Ixia and Iris, or Fleur-de-lys. These with Crocus, Gladiolus, Antholyza, and a sew others not easily met with, agree in having a spathe or sheath instead of a calyx; a corolla of six petals, or at least cut into six parts; generally three stigmas, or one that is trisid; and a triangular, trivalvular, trilocular capsule to inclose the seeds: they have also long narrow leaves, something resembling those of grass. Linnæus calls

<sup>·</sup> Corrupted into Flower-de-luce.

them Ensiform, or sword-shaped?. These plants are very nearly allied to the liliaceous tribeq, and are indeed inrolled in it by the generality of authors who have aimed at

framing a natural arrangement.

Take any species of Iris, either the Iris. bluer or white torts, which you have so abundantly in the borders of your shrubberies and plantations; or else the tyellow one, common in wet places, and usually called flag. In the first place you will obferve, that, whether the flowers are open or cloted, each has its own sheath, separating it from the others. The corolla at first seems to consist of fix petals, but you will quickly fee that the parts are all united at the base: the three outermost of these parts or petals are bent downwards, and thence are called falls; the three inner ones stand erect, and have the name of standards. In the centre of them are three other petals, as they feem to be; but in reality they are the stigma thus divided into three parts: and under each division you will detect a fingle stamen lurking, with the filament bent along with the stigma, and terminated by a large oblong, flatted anther:

P Hence in his Natural Orders he has kept these together, with the addition of some others, under the title of Ensatæ.

<sup>9</sup> See Letter I.

r Iris germanica Linnæi. Blackw. t. 69.
s Iris florentina Linnæi. Mill. fig. t. 154.

<sup>&</sup>lt;sup>t</sup> Iris pseudacorus Linnæi. Curtis, Lond. III. 4.

for the germ, you must search below the flower, and there you will find it a green oblong body; which, when the flower is faded and fallen, becomes in most species a three-cornered capfule, opening by three valves, and having the feeds ranged in three cells. We have not yet noticed a fet of fmall bodies forming a villous line along the middle of the reflex petals; but this you perceive is not common to all the species; your blue and white iris having it, but not your yellow flag: it cannot, therefore, be a mark of the genus. However, it may ferve the purpose of subdividing it, or furnishing a specific character. When you have finished with the fructification, you will remark that the leaves are very narrow in proportion to their length, and that they are not unaptly termed enfiform from the fimilitude of their shape to that of a broad-sword. If you can have the heart to pull one of these fine plants out of the ground, you will fee that the roots are not fibrous, but oblong and fleshy: I guess, however, that you will take my word till the autumn, when the gardener will be removing some of them, or at least exposing their roots, when he digs his borders.

You may distinguish the blue or German, the white or Florentine, and the yellow or marsh Iris, specifically thus: The two first have the corollas bearded; the first and third have several flowers upon the stem;

the

the fecond has only one or two flowers, and the peduncles are not fo long as in the first; the third has the corollas beardless, and the interior petals less than the divisions of the stigma". But why all this parade, fay you, when we know them by their hues-blue. white, and yellow? Trust not too much to colour, fair cousin. What if an Iris were to present itself with blue flowers, and only one or two on the stem, or without beards; or with the flowering stem shorter than the leaves—would fuch be of the same species, merely because the corolla is of a blue colour? No, furely: and we pay more respect to these circumstances than to colour, not because we esteem them more, but because they are more certain and permanent.

The Chalcedonian Iris v has stems two feet and an half high, supporting one very large flower; the three standards are very broad and thin, with black and white stripes; the three salls are of a darker colour; this is one

of the bearded forts.

Among these handsome specious plants, let us not forget the humble Persian Iris w, seldom rising three inches from the ground, but beautiful in its colours, fragrant in its scent, and slowering at a time when sew

<sup>&</sup>quot; They are all three diffinguished from some other species by the flowering stalk standing up superior to the tips of the leaves.

Iris Sufiana Linnæi. Curt. Magaz. 91.

W Iris Perfica Linnæi.

beauties dare trust themselves to dubious skies and inclement air. One or two flowers come out together: the standards are of a pale sky blue; the salls are of the same colour on the outside, but the lip has a yellow streak running through the middle, and on each side are many dark spots with one large deep purple spot at the bottom: they have no beard. The leaves are hollowed like the keel of a boat, and are about six inches long. You will be glad to entertain this pretty dwarf, when there is little else to amuse you in this way besides crocuses and snowdrops.

I have fent you this little no legay of handfome flowers, to make you amends for all the dry chaff and hay with which I fatigued

you in my last.

\* February. This is figured in Curtis's Magazine, n. 1. And feveral other forts are figured in that elegant work—as I. pumila t. 9.—variegata 16.—versicolor 21.—fibirica 50.—fpuria 58.—ochroleuca 61.—fambucina 87.—martinicensis 416.—chinensis 373.—cristata 412.—pavonia 168. I. Pseudacorus & fætidissima in Engl. Bot. 578. & 596. By this affemblage we are much helped in distinguishing the species.

## LETTER XV.

OF THE CLASS TETRANDRIA.

July the 8th, 1774.

CONSCIOUS, dear cousin, that the nosegay of my last was too small to employ you long, I have hasted to send you the fourth class, which is rather more numerous than the third in the genera, of which it contains eighty-five; but far less so in the species, there being no more of these than three hundred and ninety.

You will have fome examples in this class of aggregate flowers, the general nature of which I explained to you before y but you will be perfect mistress of it, I am persuaded, when you have considered the structure of the Teasel and Scabious. These and all others of this natural order have monopetalous corollas, succeeded by one seed, to which they are superior. A number of these are included within one common calyx, as in the compound flowers, from which they differ, in having the stamens four in number, and totally distinct, with a calyx proper to each little flower. They might, however, easily be consounded

y In Letter VI. clish and quil "

with compound flowers, if the general form and appearance only were attended to.

Dipfacus The two genera of Teafel and Scabious agree in having the common calyx polyphylous, or confifting of many leaves. The first has chaffs between the flowers on the receptacle, or common base of them all; the form of which is conical. The second has these chaffs in some species, but in others the receptacle is naked; the form of it is convex: it is remarkable for a double calyx to each little flower, besides that which is common to the whole. The leaves of the calyx are very long in the teasel, and in several rows in the scabious.

Such are their principal generic distinctions. Common teasel is separated from its congeners by its sessile leaves, which are serrate or toothed about the edges. The conical head of the teasel is surnished with stiff beards, which in the wild fort are straight, but in the cultivated hooked. This difference did not seem to Linnæus considerable enough to make them specifically distinct. Haller, Jaquin, and others, are of a different opinion; and it is now generally allowed that the cultivated teasel is of a species distinct from the wild one.

Scabiofa. Of Scabious there are no less than thirty-

Dipfacus fullonum Linn. Ger. 1167. 1. Mor. 7. 36. 1.

four

<sup>&</sup>lt;sup>2</sup> Dipsacus sylvestris. Curtis, Lond. III. 9. Ger. 1167. 2.

four species. The genus divides conveniently into fuch as have the corollas of the little flowers divided into four, and fuch as have them divided into five fegments; of the first there are fourteen, of the second twenty species. Of our three wild forts two are in the first division, and one in the last. The common field Scabious' is a large, tall plant; the stalk is hairy: the lower leaves are fometimes almost entire; fometimes they, as well as the leaves upon the stem, are pinnatifid. The outer flowers are larger, and have the corolla deeper cut than the middle ones, and the outer fegments are also largest: they are of a pale purple colour.

The other species with quadrifid corollas is called Devil's-bit', because it has a short tap root, which appears as if the end were bitten off. The stalks of this are not so high, nor are they branching as in the first: they generally send out two short peduncles from the upper joint, opposite to one another, each terminated by one small blue flower, as is the principal stalk by one larger; the little component flowers are not irregular as in the former. The leaves are simple and entire (except some on the middle of the stem, which have a few teeth), oblong and drawing to a point at each end. This species grows in pastures and woods,

<sup>c</sup> Scabiosa succisa Lin. Curtis, Lond. III. 10.

<sup>&</sup>lt;sup>b</sup> Scabiola arventis Lin. Curtis, Lond. IV. 13. Engl. Bot. 659.

and flowers later than the first, which is common in corn-fields, and not uncommon

in pastures.

Small Scabious<sup>d</sup>, besides having quinquesid corollas, is distinguished from the two others by having the leaves next the ground ovate and notched about the edges, whilst those upon the stem are pinnate; towards the bottom the pinnas are broader, but in the upper ones very narrow: there are about eight pairs of these, and the terminating leastet is large. The aggregate slower is produced single, on a long peduncle, the outer little slowers larger, and very irregular, as in the sirst species, of a pale blue colour. It is common in pastures, especially where the soil is chalky.

Before you are got thus far, I am perfuaded your own mind has suggested to you that a plant with dark purple flowers, and a strong sweet odour, which your gardener fows every year in the borders, is of this genus. The name of Sweet Scabious has not led you, who are not governed by mere names, to suppose this, but the evident similitude in the structure. An accurate examination of the flower will confirm your suspicion; and you will find it to be one of those which have quinquesid irregular corollas: the-receptacle of these is oblong; the common calyx consists of

f. 1. Scabiofa columbaria Lin. Fl. Dan. t. 314. Pl. 11.

twelve linear folioles, of the length of the aggregate flower, and bent back: the leaves are finely cute. The colour of the corolla varies from black to pale purple, red, and variegated, and fometimes the main flower is furrounded by a fet of very fmall ones on flender peduncles, as in the Hen and Chicken Daily; but all these are confessedly no other than feminal varieties: though now to common with us, this plant is originally from the Indies.

This class comprises another natural order of plants, entitled Stellated, from the manner in which the leaves grow upon the stem, several together in sets one above another, radiating like the points of a star, as it is commonly represented. I must obferve to you, that though in this case and in many others, a class or order takes its name from an obvious or striking circumstance in its structure, vet it does not follow that all plants which have that structure are to be looked for there, or that this is the only or even principal reason of their being kept together. When a plant of this or that general appearance presents itfelf, you may reasonably presume that it ranks in this or that order; but outward appearances must not carry you beyond prefumption, and it is the structure of

e Scabiosa atropurpurea Lin. Ger. 724. 16. Curt. Mag. 247. M 2

the fructification that must determine you at last f.

In the Stellated plants the structure is this: the calyx is extremely minute, divided into four parts, and permanent: the corolla is monopetalous, divided into four fegments; the stamens are four in number; the germ is double, and below the flower; the style is bisid; the fruit is globose, and contains two seeds. The stalk is quadrangular.

All the genera of this order refemble each other so much, that some authors have reduced them into one. Madder has a bell-shaped corolla, succeeded by two berries with one seed in each. Sherardia and Wood-roofs have sunnel-shaped corollas: the first has a little crown to the seeds, the second has them slobose without any grown. Can

has a little crown to the feeds, the fecond Salium. has them globose, without any crown. Galium has a salver-shaped corolla, and two roundish feeds. This last genus has twenty-fix species, twenty of which have the fruit smooth; in the remaining six it is rough. The number of leaves in each star or whorl, together with the shape of them, gives the principal specific distinctions.

White

See what was faid upon this subject with respect to the Elder in Letter V. I must add that use and practice are necessary to give the proper tact in natural objects as well as in the works of art: the similar desand analogies that ignorant persons find being usually truly ridiculous.

<sup>&</sup>amp; Asperula odorata. Curtis, Lond. IV. 15.

White Galium, or White Ladies Bedstrawh, has four leaves in a whorl towards the bottom of the stem, and six narrower ones higher up. Great Ladies Bedstrawi has eight, a little notched about the edges, ovate in form, and terminating in a point or little hook. Yellow Ladies Bedstraw has also eight leaves, but they are very narrow, and furrowed; the flowering stalks are very short, and the corollas are yellow. The first grows in moist meadows, and by rivers sides; the fecond in hedges, and on heaths among the bushes; the third is very common in pastures, on balks, and by way sides. These three all have smooth seeds. The common Galium, known by the name of Goole grass or Cleavers, every body knows to have rough feeds, by their flicking to the clothes as we pass near the hedges. The leaves also are rough, lance-shaped, and eight in number. The flowers of all the species, and indeed of the whole tribe, are very small; but the plants are known at first fight by their air.

The Plantains are also of the first order Plantago of this class Tetrandria: they are numerous, for there are twenty-four species of them.

As a great number of small flowers grow together in a spike or oblong head, you

h Galium palustre Lin. Fl. Dan. 423.

i Galium Mollugo Lin. Fl. Dan. t. 455.

\* Galium verum Lin. Curtis, Lond. n. 63. Mill.

Galium Aparine, Curtis, Lond. II. 9. Fl. Ruft. 104.

must separate one of them to examine the parts of the fructification distinctly. You will then find that each of these small flowers has a quadrifid calyx and corolla, with the border of the latter reflex: the filaments are remarkably long: and the seed-vessel is a bilocular capsule, opening horizontally,

and placed above the receptacle.

The Great m, and Ribwort Plantains are doubtless well known to you; the first so common by way fides, and the fecond in pasture grounds. The Great Plantain is distinguished by its oviate, smooth leaves, and its round, naked flowering-stalk o terminated by a long spike of flowers lying close over each other P. Hoary Plantain 9 is nearly allied to this, but the leaves are longer, and white with hairs; the spike is cylindric, but shorter and thicker than in the first. Ribwort Plantain has the leaves lance-shaped; a short, naked, ovate spike; the scape angular and twisted. This and the other species have the leaves marked lengthwife, with very prominent ribs or nerves.

By submitting to examine these plants, which you were already acquainted with, you will acquire a facility in discovering such as are strangers to you; for you have

2 Plantago media Lin. Curtis, Lond. IV. 14.

m Plantago major Lin. Curtis, Lond. II. 11.

n Plantago lanceolata Lin. Curtis, Lond. II. 10. Pl. 11. f. 3. Fl. Ruft. t. 67. Engl. Bot. 507.

This Linnaeus calls fcapus, from its refemblance to the thaft of a column.

too much fense to despise them because they are common, or destitute of beauty: in confidence of this, I have been studious to felect rather fuch plants as you may readily meet with, and are proper for examination, than those that are most rare and valuable. If you were in the neighbourhood of a famous botanic garden, I might be nicer in my choice, and at the same time present you with greater variety; but perhaps, after all, I might not be more useful, or you more amused: at least I thall hope for the continuance of that indulgence a little longer with which you have hitherto honoured mer.

But to return to our bufiness; there is a plant of this fourth class and first order, which I must not omit presenting to you, were it but for the name's fake. Ladies Alche-Mantle has a calvx of one permanent leaf, milla. divided into eight fegments, four of which are larger, and four fmaller; it has no corolla; and only one little feed to each flower. There are three species of Ladies Mantle. 1. The Common, 2. The Alpine, and

M

3. The

<sup>\*</sup> Students in Botany who live in or near London, of come occasionally to the great city, will be happy to profit by Mr. Curtis's excellent Garden at Brompton, where a confiderable number of plants is arranged and named, so that he that runs may read.

<sup>1.</sup> Alchemilla vulgaris Lin. Mor. Hist. s. 2. t. 20. f. 1. Mill. fig. pl. 18. Eng. Bot. 597.

<sup>2.</sup> Alchemilla alpina Lin. Fl. Dan. t. 49. Engl. Bot. 244.

3. The five-leaved. The first is known by its simple lobate leaves, nicely serrated about the edge, and divided into from eight to twelve greater parts; before the leaf expands, it is folded or plaited at each of these divisions, and hence the name. The flowers grow in bunches, are inconsiderable in point of fize, and also of colour; for, having no corolla, they are only green, or what Botanists call herbaceous. It is an humble but an elegant plant, and grows in high pastures, but not common.

Alpine Ladies Mantle is much more elegant than this, with its shining silky leaves, which are digitate, and indented at the end: the folioles or component leaves vary in number from five to nine. The third species is very uncommon: it is a small plant, quite smooth, with digitate leaves, but each of its five folioles divided half way into several smaller ones.

The fecond order of this class has a fingular plant, Cuscuta or Dodder. It is without leaves, has a stalk slender as a thread, which would trail along the ground did it not lay hold on some plant stronger than itself for support; not content with support, where it lays hold, there it draws its nourishment; and, at length, in gratitude for all this, strangles its entertainer! I imagine this account will not bespeak your

<sup>3.</sup> Alchemilla pentaphyllea Lin.

affection for Dodder' If you will be at the pains of difembarrassing a poor suffering bean from its entangling stalks, you will see that the flowers come out in sessile knots; that each of these has a calyx divided half way into sour or sive parts; that the corolla is of one petal divided into sour or sive segments at the edge; and that the seed-vessel is a bilocular capsule. This parasite, as Linnæus justly calls such plants, fastens itself about beans, nettles, clover, flax, heath, &c. and feeds upon them by means of innumerable teats or glands which it inserts into the pores of its supporter's bark.

The *Pondweeds*, which are many and fufficiently common, will ferve for an infrance of the third order. If your own fish-ponds are kept too clean to furnish these plants, you may probably procure them from some of your neighbours: or, if they were worth the carriage, I could send you abundance from our moat. You will know them by the leaves lying slat upon the water; and by the stem's pushing up a spike of inconsiderable flowers, that have no calyx, a corolla of sour deciduous petals, sour

<sup>&</sup>lt;sup>e</sup> Cuscuta Europæa Lin. Fl. Dan. 199. The divisions of the calyx, and corolla, and the stamens, are five in the British species; ours therefore is C. Epithymum, and, according to the strict laws of the artiscial system, should appear in the next class. It is sigured in Fl. Dan. 42. See Engl. Bot. 55 and 378.

germs terminated by obtuse stigmas, without the interposition of any style, and be-

coming in time four roundish seeds.

The broad-leaved fpecies is one of the most common, and is known by its oblong ovate leaves. Perfoliate pondweed u has heart-shaped leaves embracing the stalk, and grows in running waters. Curled pondweed has lance-shaped, waving leaves. notched about the edges, and standing alternate upon the stem: this is found both in running and stagnant waters.

But of these enough-don't hazard getting wet or catching cold, in fearch of them. If any of these plants which I have hitherto recommended to your notice elude your fearch, or have passed their stated time of flowering before you find them, note them down for next year: fo adieu, dear coulin. data see where have there are a

## LETTER XVI.

THE FIRST ORDER OF THE FIFTH CLASS, PENTANDRIA MONOGYNIA.

March the 25th, 1775.

Y indisposition of last autumn has given you ample leisure, dear cousin, to make yourself mistress of the general arrangement of plants, and of the first four classes in particular. Since it is your earnest desire, I have resumed my former prate as early as possible, that nothing may escape us this season. We have now a large class to encounter with, containing more than a tenth part of the vegetable world; for it has two hundred and sixty-one genera, and one thousand five hundred and five species. It includes, as you may suppose, several natural orders; and some species are even now ready for examination.

We will open the year, by your leave, Primula. with the Primrose, which has its name from being one of the first flowers that blow. This, with some others that resemble it, forms a natural order, entitled for the same reason Precia, and agree in having a monophyllous, quinquesid, permanent calyx; a monopetalous, quinquesid corolla; and a

capfule for a feed-vessel, superior or inclosed within the calyx. The characters of the genus are, an involucre under the flower, or knot of flowers; the corolla funnel-shaped or salver-shaped, with the tube cylindric, and open at the top; the stigma globose: the capsule unilocular. The species x is distinguished by its pentagonal calyx, its cylindric oblong capfule, and the wrinkled furface and indented edges of its leaves. The three principal varieties, if they are but varieties, are thus commodiously feparated. The Primrosey has one flower on a naked stem, and the corolla falver-shaped, The Ox-lip has feveral flowers on one naked stem, and the corolla salver-shaped. The Cowllipa has many flowers on a naked stem. and the corolla funnel-shaped. The vellow of the two first is very pale; the corolla of the primrose is much the largest; that of the ox-lip a middle fize, between the two others: the simple unbranched flowering ftem of the primrose is weak, and rather a peduncle than a stalk; the scape of the ox-lip is fometimes near a foot high, and strong; that of the cowslip is generally

<sup>\*</sup> Comprehending primrofe, ex-lip, cow-flip, and polyanthus.

y Primula acaulis *Lin.* vulgaris *Hudson*. Fl. Dan. 194. Engl. Bot. t. 4.

<sup>&</sup>lt;sup>2</sup> Primula vulgaris β Huds. Fl. Dan. 434. Engl. Bot. t. 513.

<sup>&</sup>lt;sup>2</sup> Primula veris Lin. & Huds. Fl. Dan. 433. Engl. Bot. t. 5.

lower and weaker. I do not know whether I dare to tell you that all the beautiful forts of Polyanthus, by you prized so much, are but an accidental variety of this species, which is certainly much disposed to vary even in its wild state. Thus the primrose has fometimes two flowers together, or changes to green, or to red, or doubles its corolla; the ox-lip fometimes has very few flowers, and they are nearly as large as a primrose; and the cowslip has frequently red flowers, then much refembling a small polyanthus. Abiston attivi aniton a

See now by how many steps you arrive at a knowledge of these plants. You first determine their class and order, by seeing that they have five stamens and one pistil: having still an hundred and fifty-five genera to encounter, you next lettle what lubdivision of the order they range under; and finding that the corolla is monopetalous, inferior, and succeeded by a vessel inclosing the feeds, you are reduced to feventy-three genera. Next you discover that they are of the natural order of Preciæ, which leaves you but ten genera to choose out of. You are now got within fo fmall a compass that it cannot be very difficult to alcertain the genus, the species which are ten in number, and the subordinate varieties. I do not make all this parade, in order to enable you to discover a plant which you were perfectly acquainted with beforehand, but to shew you how you are to proceed with a plant you do not know, from this inflance of one which you do.

Or you may take it thus: You have a plant in flower, which for the present we will suppose you to be unacquainted with. You first examine the stamens and pistils: and by the number of these you determine your plant to belong to the fifth class and the first order. You next consult the subdivisions of that order, and find it belonging to that which has monopetalous inferior corollas, with the feeds inclosed in a vessel. Seeing farther that your plant has a monophyllous calyx cut into five fegments, that the corolla is also divided in the same manner; this, added to the foregoing circumstances, shews you that it ranges under the natural order of Preciæ. Here remarking an involucre under the flowers, the tube of the corolla cylindric, and open at top, and the capfule unilocular or one-celled, you are affured at length that your plant is of the genus Primula. But finding that the leaves, instead of being wrinkled, are perfeetly smooth, fleshy, and either entire, or sharply notched about the edges, you are well affured that it is a distinct species; and upon inquiry discover it to be the Auriculab, the elegant, the powdered auricula, so much esteemed by florists, and so various

b Primula Auricula Lin. Ger. 784. 5, 6.

in the fize and colours of its corolla, when in a state of cultivation.

All the other plants of this natural order Meadia. are pretty, if not specious. Meadia, perversely altered by Linnæus to Dodecatheone is an American plant, but flowers well and early in our climate. It has a rotate or wheel-shaped corolla with reflex petals: the stamens fit upon the tube; and the capfule has one cell only, and is oblong. This is fufficient for the complete detection of the plant, fince there is only one known species. The leaves, however, are fmooth; the flowering stems are naked, eight or nine inches high, and sustain many flowers, each of which has a long flender peduncle, which is recurved so that the flower hangs down-; the corolla is of a beautiful light purple. If you have not this plant already in your garden, procure it against next spring; you will be pleased with the structure and appearance of it.

Cyclamen resembles Meadia in its wheel- Cyclashaped reflex corolla, but the tube is globu- men. lar and remarkably short, with the neck prominent; the stigma, which was obtuse in that, is acute in this. The feed-vessel is roundish and fleshy, inclosing several angular feeds: Linnæus calls it a berry covered with a capfular shell. There are several fpecies or varieties of cyclamen: for it is doubtful whether they are positively dis-

Curtis's Magaz. 12. Mil. fig. pl. 174. Pl. 12. f. 2. Thornton illustr. n. 9. eabtorlymyn - pe 5

tinct or not. The most common has heart-shaped angular leaves, marked with black in the middle. The flowers appear alone, before these, rising immediately from the root: when they fall, the peduncles twift up like a fcrew, inclosing the germ in the centre, and lie close to the ground among the leaves, which grow very thick together, and protect them all winter. The common colour of the corolla is red, but it varies to purple and white. There is one fort which has the leaves purple underneath; and another which has the veins only purple, and the upper fide veined and marbled with white: the flowers white with a purple base. The Persian fort has leaves like the last in colour, but quite entire about the edges, the flowers large, pale purple with a bright red or purple base. All these, and other differences, whether specific or not, make a most agreeable variety, and are very beautiful.

There are two wild plants of this natural order which I must recommend to your infpection for their beauty. They grow in the water, and therefore you must procure them by another hand.

Menyan- Marsh Trefoil, Buckbean or Bog-beans, thes. will discover itself to you immediately by

d Cyclamen Europæum Lin. Engl. Bot. 548 C. coum is figured in Curt. Magaz. t. 4 — Perficum, in t. 44. Miller's fig. pl. 115.

Menyanthes trifoliata Lin. Curtis, Lond. IV. 17. Engl. Bot. 495.—nymphoides, idem 217.

the corolla being fringed all over; it is funnel-shaped, with a short tube, and the border divided beyond the middle; the colour is white, but red on the outside; the stigma bisid; and the seed-vessel a capsule of one cell. The species is distinguished by its ternate leaves; whence, and from its situation, it has the name of Mar/h-trefoil; and because each of the component leaves is of the size and shape of a bean-leas, it is also called Buckbean or Bogbean. The slowers grow in a loose spike at the top of the stem.

Water Violet has a salver-shaped corolla Hottonia

not fringed, the tube longer than in the last, the colour white or faint purple, with a yellow eye: the stamens are placed upon the tube of the corolla; the stigma globose; and the seed-vessel a capsule of one cell, as in the last. The leaves are wholly immersed in the water, and finely pinnate; the slower-stem is naked, and rises five or six inches above water; towards the top are two or three whorls of slowers, and it is terminated with a cluster of them; the whole forming a kind of conical spike.

Another natural order of this class contains the plants entitled Asperifoliæ or rough-leaved. These are not so beautiful as the last; but you are by this time become too good a naturalist to be led away by gaudy colours or specious appearances. Though roughness of the leaves and stem be a general

N

<sup>&</sup>lt;sup>8</sup> Hottonia palustris Lin. Curtis, Lond. I. 11. Engl. Bot. 364.

character of this order, yet it is more necesfary that the following character should be found in the fructification. The calyx is of one leaf, divided into five fegments, and permanent: the corolla is monopetalous, divided also into five segments, tubulous, and extending below the germs: the five stamens grow from the tube of the corolla: and there are four naked feeds to which the calyx ferves as a capfule. We may remark farther, that the leaves are placed alternately, or without order, on the stem; and that the spike of flowers, before they open, is reflex. With to ample a train of circumstances to direct you, there cannot be much difficulty in knowing when you meet with one of this rough-leaved tribe of plants; especially as they wear the same dress, and have a strong family likeness.

Out of eighty-three species, which this order contains, you may perhaps know some of the following, and from them you will have an idea of the rest. Heliotrope or Turnsole, Mouse-ear, Scorpion-grass, Gromwell, Alkanet, Hound's-tongue, Pulmonaria, Comfrey, Cerinthe, Borage, Bugloss, and Viper's Bugloss. If you examine the corolla of these plants, you will observe that some of them have five scales in the tube of it, whilst others have none; this circumstance, together with the shape of the corolla, will furnish the principal generic distinctions. Thus Gromwell, Pulmonaria, Cerinthe, and

Viper's

Viper's Bugloss, have the tube of the corolla naked; the rest have the five scales, Heliotrope and Mouse-ear Scorpion-grass have falver-shaped flowers; Gromwell, Alkanet, Hound's-tongue, Pulmonaria, and Bugloss, have funnel-shaped flowers; in Comtrey and Cerinthe the corolla is ventricose, swells or bulges out towards the top; Borage has a rotate corolla; and in Viper's Bugloss it is an irregular kind of bell-shaped corolla. Heliotrope has the scales; but the top of the tube is not closed by them, as it is in the Mouse-ear Scorpion grass, Alkanet, Hound'stongue, Comfrey, Borage, Hound's-tongue has flat feeds fixed to their style by their inner side only. Pulmonaria has a pentagonal or prismatic calyx. Cerinthe has only two hard, shining, bilocular feeds. Bugloss has the tube of the corolla bent.

Common Turnfole has the leaves ovate, Helioentire, wrinkled, and covered with a nap; tropium. the lower spikes of flowers are single, and the upper ones double. The colour of the corolla white, with a greenish eye, and sometimes light red. This is an annual

plant: 500 4

Peruvian Turnfole<sup>1</sup> has a shrubby stem; the leaves of a long ovate form, wrinkled and rough, on short petioles; the flowers are produced at the end of the branches in

N 2 dask one thort

h Heliotropium Europæum. Lin. Jacq. austr. 3. t. 207. Heliotropium Peruvianum Lin. Mill. fig. pl. 144. Curt. Magaz. 141.

fhort spikes, growing on clusters; the peduncles divide into two or three others, and these again into smaller ones, each sustaining a spike of pale blue flowers, which have

a peculiar odour.

Myosotis Mouse-ear Scorpion-grass is common both in dry pastures and heaths, and by the sides of ditches and streams; in the former it is hairy, in the latter smooth, with the flowers much larger, and extremely beautiful when seen sufficiently near, of a most elegant blue with a yellow eye. Linnæus distinguishes this species by the smoothness of the seeds, and by the tips of the leaves being callous.

Lithospermum The true Gromwell 1, which name is a corruption from Gray Millet, is not very common; it affects dry soils, especially chalk, and is found chiefly in woody places, or among bushes. You will know it by its whitish, shining, oval, hard seeds; which latter quality gave occasion to the Latin name, from the Greek, Lithospermum. Or if it be not far enough advanced to show the seeds, observe that it is a much larger and more branching plant than the next; the leaves are lance-shaped; the flowers are

<sup>k</sup> Myosotis scorpoides Lin. Curtis, Lond. III. 13. Engl. Bot. 480.

small, and come out single from the axils

m Stone-feed.

Lithospermum officinale Lin. Mor. Hist. s. 11. t. 31. s. 1. Ger. 609. 2. Engl. Bot. t. 134.—arvense Engl. Bot. t. 123.

of the leaves on short peduncles; the corolla is white or yellowish, with a greenish tube.

Corn Gromwell<sup>n</sup> is a common weed among corn, and differs from the former in its wrinkled, conical feeds; the leaves also are ovate and sharp-pointed; the flowers are chiefly on the top of the stem among the leaves; the corolla is white, with the tube swelling at top. Both species have the corollas scarcely extending beyond the segments of the calyx; and both have the roots tinged with red, whence the latter has the name of Bastard Alkanet.

Hound's-tongue is a large plant that grows Cynocommon by hedges and way-fides; it has a gloffum. It frong fimell like that of mice. The corolla is of a dirty red, or the colour of blood that has stood some time. It is distinguished from the other species by the stamens being shorter than the corolla; the leaves broad lance-shaped, nappy, and sitting close to the stem without petioles.

Comfrey p is common by water-fides. The Symphyleaves are large, long, hairy, and ending tum. in a point; from their base on each fide runs a border down the stalk q. From the

upper part of the stalk come out some side-

<sup>&</sup>lt;sup>n</sup> Lithospermum arvense Lin. Fl. Dan. 456. Mor. f. 7. Ger 610, 4.

<sup>4</sup> This is what Linæus calls decurrent.

branches, with two smaller leaves, terminated by loose bunches of nodding flowers; the corolla of a yellowish white, in some

places purple.

distinguished by the larger fort having obtuse, open corollas; the less having sharp, close corollas. The leaves of the first are sea-green spotted with white; it varies with prickly and smooth leaves, with yellow and purplish red corollas. It grows wild in Italy, the south of France, Germany, and Switzerland. The second has more slender stalks; the calyx large, the corolla small and yellow. This is found naturally in the Alps. Both are not uncommon in gardens.

Borago. Borage<sup>t</sup> is an annual plant, which comes up in your kitchen garden without the care of the gardener. The whole plant is rough; the leaves are large, and broad lance-fhaped. The flowers come out in loofe, naked bunches, on long peduncles, at the end of the stalks: the calyx, with the corolla, spreads out quite flat; the colour of the corolla is a fine blue, which sometimes fades to white, or changes to red.

Lycopsis. Bugloss is common among corn, and by

<sup>&</sup>lt;sup>t</sup> Cerinthe major Lin. Mill. fig. 91. Curt. Magaz., 333.

way-fides: a very rough plant, with blue corollas veined with white.

Viper's Bugloss v is a much larger plant Echium. than this, with a large handsome spike of blue flowers. The stalk is very erect and spotted; the leaves lance-shaped, the lower ones petiolate, the upper fessile. It is common among the corn in fome countries; also in some pastures, by way-sides, and on walls.

You will find some plants of this fifth class and first order which have a bell-shaped corolla of one petal. If they have a permanent calvx divided into five parts, and a capfule for a feed-veffel, they belong to a natural order entitled Campanaceæw. Three very large genera\*, besides some others, belong to this order.

The genus Convolvulus, is diffinguished Convolfrom all others by its large spreading, vulus. plaited corolla, with the edge either marked with ten notches, or flightly quinquefid; two stigmas; and a capfule wrapped up in the calyx, generally bilocular, with two

roundish seeds.

From this genus I will felect two wild

w Bell-flowers.

\* Convolvulus, Ipomæa, and Campanula: the first has fixty-four, the second twenty-two, and the third fixty-fix species.

So called from twining round any thing it comes near; this property however is not common to all the

species.

and

V Echium vulgare Lin. Fl. Dan. 445. Ger. 802. 2. Engl. Bot. 181. Fl. Ruft. 136.

and two cultivated species, for your examination.

Small Bindweed<sup>2</sup>, which is fo common a weed among corn, has fagittate leaves<sup>2</sup> acute both ways, and one flower upon a round long peduncle. The weak stalks trail on the ground, unless they meet with some other plant to support them; the corolla is either white, or red, or variegated; and if the plant came from India it would be culrivated for the beauty of the flower: I do not however recommend you to grow fond of it, for it creeps intolerably at the root.

Great Bindweed<sup>b</sup> has fagittate leaves as well as the last, but truncate or cut off behind; the flowers come out single also, but on square peduncles. This is a much larger, stronger plant than the other, rising in hedges or among bushes and shrubs, ten or twelve feet high: the corolla is very large, and always pure white; immediately under the calyx is a large heart-shaped involucre of two leaves. The former species has these two leaves, but they are very narrow, and in the middle of the peduncle,

Purple Bindweed<sup>c</sup>, an annual species cultivated in flower gardens under the name of Convolvulus major, has heart-shaped undi-

<sup>&</sup>lt;sup>2</sup> Convolvulus arvensis Lin. Curtis, Lond. II. 13. Fl. Rust. t. 89. Engl. Bot. 312.

a Shaped like the head of an arrow.

b Convolvulus sepium Lin. Curtis, Lond. I. 13. Pl. 12. f. 3. Fl. Rust. t. 88. Engl. Bot. 313.

<sup>&</sup>lt;sup>c</sup> Convolvulus purpureus Lin. Ehret, pict. t. 7. f. 2. Curtis's Magaz. 113.

vided leaves, the feed-veffels hanging down after the flower is gone, and the peduncles swelling. This, if supported, will climb to the height of ten or twelve feet. Though the most usual colour of the corolla is purple, yet there are varieties white, red, and whitish blue.

Tricolor Bindweed<sup>d</sup>, or, as it is vulgarly called, Convolvulus minor, has lance-shaped, smooth leaves, a weak falling stalk that never climbs, and the flower coming out singly. The corolla is a beautiful blue with a white eye; but sometimes all white or variegated. This is also annual. Its native country is Portugal. The former is wild both in Asia and America.

This genus contains several remarkable plants; as, Scammony, Turpethum or Tur-

bith, and Jalap.

Ipomæa has rather a funnel-shaped than a campanulate corolla; a globose stigma, and atrilocular capsules; but the plants that range under this genus being natives of the West Indies, and consequently requiring much heat to raise and preserve them, may probably not come within your view; and therefore I shall not enlarge upon them.

In Campanula you will of course expect Campato find a campanulate or bell-shaped co-nula. rolla; but it is worth your observation that

d Convolvulus tricolor Lin. Curtis's Mag. 27. Conv. Scammonia Lin. Mill. fig. 102.

f Mill. fig. 214. Curt. Magaz. t. 221 & 244.

the bottom of it is closed with five valves concealing the receptacle, and that the stamens take their rise from these valves. The stigma is trifid, and the seed-vessel is a capsule, below the slower, having three or sive cells, and at the top of each a hole, through which the seeds are scattered when ripe. You see by this time how curious and how various the structure of the parts of sructification is. By thus examining them singly, and comparing them one with another, you will in time grow an eminent Botanist, and acquire a facility in determining the genus, species, analogy, and connexion of vegetables.

There is a little Bell-flower that grows frequent in dry pastures, and on almost every heath and common, with its nodding blue corolla answering well to its name. The Botanists have conspired to call it round-leaved Bell-flower; for what reason perhaps you will wonder, since you will discover no leaves upon the stem but what are linear, or very long, narrow lance-shaped: if however you take a young plant, or at least one in full vigour, and search among the grass close to the ground, you will see these leaves, which are not so properly round as hearth or kidney-shaped. This fort flowers towards the latter end of the summer, and all the autumn, till frost puts an

E Campanula rotundifolia Linnæi. Curtis. Lond. IV. 21. Linnæus.

end to it; and frequently has a white corolla. Rampionk, which was formerly cultivated for its roots to eat in fallads, is now
fo much neglected that your kitchen-garden
perhaps may not furnish it; and in its wild
state it is by no means common. This has
upright stalks, two feet high; the leaves
undulating, those next the root short, lanceshaped; inclined to oval: towards the upper part of the stem, and close to it, small
flowers are produced, with a blue or white
corolla.

Peach-leaved Bell flower<sup>1</sup> is abundant in your flower borders, both blue and white; but fince your gardener has obtained the double forts, he has probably despised the fingle one so much as to have destroyed them, and at the same time to have deprived you of the power of determining the genus: you will however know this to be a Campanula by its air; and you will determine the species by the leaves, which are ovate near the root, and on the stalk are very narrow lance-shaped approaching to linear, slightly serrated about the edge, sit close to the stem, and are remote from each other.

I remember your hall chimney used to be adorned in summer with the *pyramidal* or *steeple* Bell-flower m, strutting out like a fan,

<sup>&</sup>lt;sup>k</sup> Campanula Repunculus Lin. Engl. Bot. t. 283.

<sup>t</sup> Campanula Perficifolia Lin. Curt. Magaz. 397.

m Campanula pyramidalis Lin.

by means of a frame of little sticks. This has smooth, heart-shaped leaves serrated about the edge; those on the stem lance-shaped: the stems are simple and rush-like: the slowers come out in sessile umbels from the side of the stem. Such are Linnæus's

specific characters.

There is the Giant Throatwort<sup>n</sup>, wild, but not common, in buffy places and hedges: known by its strong, round, single stalks; its long ovate leaves, inclined to lance-shaped, slightly serrated or toothed like a saw on their edges: towards the upper part of the stalk the slowers come out singly upon short peduncles. Pray remark, that after these are saded, the seed-vessels turn downwards till the seeds are ripe, and then rise up again.

Great Bell-flower, vulgarly called Canterbury Bells, is much more common in the like places. This has stiff, hairy, angular stalks, putting out a few short side branches. The leaves are like those of nettles, hairy, and deeply serrated on their edges: towards the upper part of the stalks the flowers come out on short trifid peduncles, and

have hairy calyxes.

Small Canterbury Bells is common in

f. 28. Ger. 448. 1. Engl. Bot. t. 12.

pastures,

n Campanula latifolia Lin. Fl. Dan. 85. Ger. 448. 2. Engl. Bot. 302.

<sup>°</sup> Campanula Trachelium Lin. Mor. Hist. s. 5. t. 3.

P Campanula glomerata *Linnæi*. Mor. t. 4. f. 40 & 43. Ger. 449. 4. Engl. Bot. t. 90.

pastures, especially in a chalky soil. In dry places it is very small, and in a moist soil will grow to the height of two feet. The stalk is hairy, angular, and unbranched; the lower leaves are broad, and pedunculate; those on the stalk long, narrow, sitting close to the stalk, and even embracing it: towards the top of the stalk, from the axils of the leaves, two or three flowers come out together, and a larger bunch terminates it: the flowers are feffile.

Venus's Looking-glass q is a Campanula, with a weak, low, and very branching stalk; the leaves oblong, and a little notched; the flowers folitary, and the feed-veffels of a prismatic form. Corn-bell-flower very much refembles this: but the stalk is stiff, and branches little; the leaves are more deeply notched, and waving; the flowers come out in parcels, and the calyx is longer than the corolla. This is a common weed among corn. These two have scarcely bell-shaped corollas, any more than another plant of this campanulate order, entitled Greek Valerian or Jacob's Ladder's, which has the Polemocorolla rather rotate, with the tube shorter nium. than the calyx, but closed with five valves, into which the stamens are inserted, as in

Polemonium cæruleum Lin. Fl. Dan. 255. Ger

1076. 5. Engl. Bot. t. 14.

Campanula:

<sup>4</sup> Campanula speculum Lin. Curtis's Magaz. 102. 2 Campanula hybrida Lin. Mort. t. 2. f. 22. Ger. 439. 2. Engl. Bot. t. 375.

Campanula: the stigma also is trifid, as in that, and the feed-veffel a trilocular or threecelled capfule, but inclosed within the flower. The circumstances that distinguish this from the other two species are, that the leaves are pinnate, the flowers erect, and the calyx full as long as the tube of the corolla: in which you fee it recedes a little from one character of the genus. It is blue, and cut into five roundish segments. I scarcely need caution you not to be misled by names, which being utually given by ignorant pertons, are very fanciful or erroneous. Thus, here, you may as well suppose Polemonium to have an affinity with a ladder as with Valerian: indeed the same circumstance of the pinnate leaves probably gave occasion to both names.

I am almost asraid to present you with a set of plants, which from their lurid, dusky, dismal, gloomy, appearance, are kept together under the title of Luridæ. They have also most of them a disagreeable smell, which, with their forbidding look, will deter our young cousin from examining them, she not being yet sufficiently tinctured with enthusiasm to go on in spite of such circumstances. Indeed I would not wish her to be too busy with some of these insane roots that take the reason prisoner, and which I can never collect and examine myself, without their affecting my head. You will consider that nature has kindly given us notice

in general of approaching danger, by means of our fentes; and accordingly fome of thefe Lurid plants are highly poisonous; most of them are so in some degree; though foil and climate may mitigate the poison, and even render them wholesome. I will felect tome of the least disagreeable in smell and appearance; or, if they be otherwise, will announce it to you. Besides the circumttances of five stamens and one pistil, these plants agree in a permanent calyx divided more or less deeply into five segments; a monopetalous corolla, divided also into five fegments, tubulous, irregular; the feedveffel bilocular, and either a capfule or a berry inclosed within the flower.

Of Verbascum, or Mullein, there are se- Verbasveral species wild, one very common, and another not uncommon. Their general characters are, that the corolla is rotate, and flightly irregular; the stamens unequal in length, bending down, and generally clothed at bottom with a coloured fringe, the stigma obtute, and the captule bivalve, and open-

ing at top.

The common species is the Great or Hoary Mulleint, which grows mostly under banks or hedges. It is a biennial plant: the first year forming its root, and a set of large, broad leaves, extremely woolly on both fides, and spreading on the ground,

t Verbascum Thapsus Linnai. Fl. Dan. 631. Mor. Hist, f. 5. t. 9. f. 1. Ger. 733. 1. Engl. Bot. 549. with

with fcarcely any petioles: the fecond year it fends up a fingle stem, sometimes five feet in height, with decurrent leaves on it, woolly as the radical ones, and on the top a close spike of yellow flowers, which have

an odour not disagreeable.

The other which I hinted at is the Black Mullein<sup>u</sup>, growing in fimilar places, abundantly in some, but by no means so extenfively. It has not so high a stem; the shape of the lower leaves is that of a heart much lengthened out, and they are petiolate; the leaves on the stem ovate, sharp pointed and fessile; all of them are pale green on the upper, and hoary on the under furface; and are indented about the edges. The stalk is terminated by a long spike of yellow flowers, formed by short clusters or spicules on the sides of the principal stalk. The corolla is yellow, with the filaments fringed or bearded with purple. It has the name of black, I prefume, merely because it is not white, like the other.

Datura.

Datura, Stramonium, or Thorn Apple, has the calyx tubulous, fwelling in the middle, five-cornered, and deciduous; the corolla funnel-shaped, spreading out gradually very wide from a long cylindric tube, into a pentangular border with five plaits: the capsule is quadrivalvular, or opens into four parts. The flowers of these are large, and rather

specious,

<sup>&</sup>lt;sup>u</sup> Verbascum nigrum Lin. Mor. Hist. s. 5. t. 9. f. 5. Engl. Bot. 59.

specious, and the capsules are remarkable for their size.

The common thorn apple v has smooth leaves, irregularly angular, and smelling disagreeably; the flowers come out from the first divisions, and near the extremitities of the branches; the corolla is white, and each angle of it ends in a long point; the capsule is ovate, covered with strong thorns, and grows erect.

Another fortw, cultivated fometimes in flower gardens, has purple flowers; it has also purple stalks, which are stouter and taller than those of the last; the leaves are also larger, and more angular and notched; the capsule is larger, but much like that of the common fort. One of them, having the capsule armed with very strong spines, has the epithet of fierce\*.

Henbane, is a very common plant, and Hyoscyhas often done mischief to such as will not amus. Suffer their appetites to be corrected by their senses. You will agree with me that the smell is sufficient to deter any person from eating it. I cannot however dispense with your examining the flower, which is really beautiful on a near view. The corolla is

v Datura Stramonium Lin. Curtis, Lond. n. 61. Fl. Dan. 436. Ger. 348. 2.

w Datura Tatula Lin.

\* Datura ferox Lin. Mor. t. 2 f. 4.

y Hyoscyamus niger Lin. Ger. 353, 1. Engl. Bot.

funnel-shaped and obtuse, of a pale yellowish colour, beautifully veined with purple. The stamens are of different lengths, and bent; and the capfule is involved in the calyx, of an oval form, and covered with a hemispherical lid, which, by falling off,

announces that the feeds are ripe.

The common wild species is distinguished from the others by its sinuate leaves, embracing the stalk, and by the slowers sitting close to it. The whole plant is covered with long hairs, from which exudes a clammy, fetid juice: the leaves are very large, and remarkably soft; and the slowers come out in a very long spike, rather on one side. It grows on banks, dunghills, and way-sides about villages, and is a biennial plant. There are other forts, but neither wild nor much cultivated.

Nicoti-

You who have such an aversion from tobacco in all the ways of using it, will not be displeased at finding it in this lurid order. Notwithstanding it is so generally taken, the oil of it is the strongest of the vegetable poisons. It is a plant however neither unornamental for your garden, nor dangerous, nor even disagreeable to examine. The effential generic characters are, that the corolla is sunnel-shaped, the border plaited; the stamens a little inclined; the stigma notched; the capsule ovate, marked with a furrow on each side, bivalvular, and opening from the top.

Common

Common or broad-leaved tobacco' is diftinguished by its broad lanceolate leaves, which are about ten inches long, and three and an half broad, smooth, ending in acute points, and fitting close to the stalks; the corollas are of a pink purple, and end in five acute points. There is a fort like this. or perhaps a variety of it, called Oroonoko tobacco, which is a large plant, the leaves more than a foot and a half long, and a foot broad; very rough and glutinous; the base embracing the stem: the corollas are of a

pale purple.

Another species, called English tobacco2. might easily be mistaken for a henbane, if you did not remark the regular form of the corolla, and the want of a lid to the capfule. It is a lower plant than the others; the leaves are ovate, entire, and on short petioles. The flowers come out in loose bunches on the top of the stalks; the corolla has a short tube, spreading out into five obtuse segments, of a greenish yellow colour. Though this has the epithet of English, you are not to suppose it to be an European plant; for it is a native of America, as well as all the other species, which are at least seven in number.

How the fame plant should come to have Atropa. the gentle appellation of Bella-donna, and

<sup>, 2</sup> Nicotiana Tabacum Linnæi. Mill. fig. 185. 1. Pl. 12. f; 1.

<sup>\*</sup> Nicotiana rustica Linnai. Blackw. t. 437.

the tremendous name of Atropab, feems strange, till we know that it was used as a wash, among the Italian ladies, to take off pimples and other excrescences from the skin, and are told of its dreadful effects as a poison. Linnæus has joined them, making Atropa the generic, and Bella-donna the specific or trivial title. The principal characters which he gives of the genus are these—the corolla is bell-shaped; the silaments grow from the base of it, are close at bottom, but at top diverge from each other, and are arched; the seed-vessel is a globose berry, sitting on the calyx, which is large.

Our fort, for there are fix species of the genus, is a great branching plant, with ovate entire leaves, and large flowers coming out among the leaves singly, on long peduncles; the corolla is of a dusky brown colour on the outside, and of a dull purple within; the stalks have a tinge of the same colour, as have also the leaves towards autumn. The berry is round, of a shining black when ripe, and not unlike a black cherry in size and colour; it contains a purple juice of a mawkish sweetness, and has frequently enticed children to taste it at their peril. I have known, however, the same poisonous effects follow from eating the young shoots

b From Atropos, the name of one of the Fates. Figured by Miller, pl. 62. Fl. Dan. 758, Ger. 340. Blackw. 564. Curtis, Lond. V. 16. Engl. Bot. 592.

of the spring boiled, as from the crude berries of autumn. Deadly Nightshade is rarely cultivated, and not common wild; it skulks in gloomy lanes and uncultivated places, but is too frequent near villages in fome countries.

You have heard of the Mandrake's Groan. and of shrieks, like mandrakes torn out " of the earth:" fuperstition having endued this plant with a fort of animal life, fatal to whoever prefumed to destroy it by digging up the root. It was famous, as opium now, for procuring sleep; whence Cleopatra fays,

-" Give me to drink Mandragera,

"That I might fleep out this great gap of time "My Anthony is away."

## And the vile Iago boafts that

"Not Poppy, nor Mandragora,

" Nor all the drowfy fyrups of the world, "Shall ever med'cine thee to that fweet fleep

"Which thou hadit yesterday."

Since Mandrake groans and shrieks when injured, it must needs have a human form: and accordingly fuch have been carried about for fale, notwithstanding the danger that attends the procuring it; but this is cunningly avoided by tying a dog to the root, and thus making the blind fury of the poor mandrake fall upon the innocent dog instead of the aggressor. These pretended mandrakes

mandrakes are faid to be roots of angelica or bryony, either cut into form, or compelled to go through earthen moulds put into the ground for this purpose: they were used in magical incantations; and though these are now pretty much out of fashion. vet I have had them very gravely offered me for fale. Linnæus formerly made this a distinct genus from the last; but on second thoughts he has made it a species of Atropac, distinguishing it from the others by its having no stems except the scapes, which support a fingle flower. The root is like that of a parinep, sometimes forked; next the ground there is a circle of large, broad leaves: the scapes or naked stalks that support the flowers are but about three inches long; the corollas are five-cornered, and of a greenish white or purplish colour; the berry is as large as a nutmeg, and of a yellowish green. The root and leaves are stinking, and the whole plant is poisonous, though in small doses it is used medicinally.

Physalis. Another genus of this same natural order is *Physalis*; the characters of it are these—the corolla is wheel-shaped; the silaments and antlers are convergent, or bend towards each other; and the seed-vessel is a berry inclosed within the calyx, which grows to a large inflated, coloured bladder. *Winter-*

e Atropa Mandragora. Mill. fig. pl. 173. Blackw. 364.

cherry, of which you have fuch abundance under your shrubs, is a species of this genus. The distinguishing marks are, that the leaves are double or conjugate, that is, come out in pairs, are entire about the edges, or but very flightly indented, and sharp-pointed; the stalk is herbaceous, and a little branching at bottom. The roots creep fo far as to be troublesome; the stalks are only about a foot high; the leaves are of various shapes, and have long petioles: the flowers are produced fingly from the axils of the stalks on slender peduncles; and have a white corolla, which, with the calyx, leaves, and stalks, is hairy, This plant, which is so humble and inconsiderable all the fummer, attracts your notice in autumn, by its great inflated calyx turning red, and disclosing the round red berry within it, about the fize of a small cherry.

But the principal genus of this natural Solanum order is the Nightshade, or Solanum, whence some authors have entitled the plants Solanum; The are no less than forty-six species of Solanum; out of which I shall felect, as usual, both some wild and cultivated forts, such especially as are either most important, or most likely to be within

your reach.

You will easily know the genus by its wheel-shaped corolla; by its large anthers closed in the middle of the corolla, and

d Phyfalis Alkekengi. Blackw. 161.

O 4

feeming to form but one body; and by its bilocular berry.

Some of the species have prickly stalks and leaves; others are unarmed: hence a commodious partition of the genus into two subdivisions.

A shrubby, tall fort, from the Madeiras, without any spines or prickles, has long been an inhabitant of the greenhouse, which it adorns with its splendid red berries all the winter: the gardeners know it by the name of Amomum Plinii; and it is often called Winter Cherrye; fuch is the dearth of diftinctive names, and fuch the confusion arifing from the want of a regular language like that which Linnæus first introduced into Botany. The leaves are lance-shaped, and have a waving edgef: the flowers grow in small umbels, close to the branches; the corolla is white; and the berries are as large as a fmall cherry, generally red, but fometimes yellow.

Another shrubby fort, without spines, is the Woody Nightshade, or Bitter-sweet, which grows commonly wild in moist hedges. This has a climbing, flexuous stalk; the lower leaves lance-shaped, the upper ones sometimes trifid: the flowers are in bunches, or branched cymes, coming out from the axils of the leaves; the corolla

<sup>·</sup> Solanum Pseudocapsicum Lip.

Linnæus calls them repand.
Solanum Dulcamara Lin. Curtis, Lond. I. 14.
Engl. Bot. 565.

revolute,

revolute, purple, marked with two shining green spots at the bottom of each segment; and the berries red.

Garden Night/hade<sup>h</sup> is also unarmed, but not shrubby. It is an herb, and annual. The leaves are on long petioles, and, being of a soft texture, are inclined to hang down. They are either of an ovate or rhomboid form, with long points angular and notched about the edges: the flowers grow on a kind of nodding umbel; the corolla is white, and the berry is black. It is a common weed on dunghills, in gardens, and other richly cultivated places. It varies with yellow and red berries, and in the form of the leaves.

Potato is of this genus, as you will be convinced, if you compare the structure of the flower with that of the other species. Linnæus characterises it by these distinctions—that the stalk is herbaceous and unarmed, the leaves pinnate and quite entire, the peduncles subdivided: the corollas are either purple or white, and the berry is large.

Tomatos or Love-applek is another species of nightshade, which is also admitted to the table, and eaten with impunity, in spite of the ill neighbourhood in which it is

<sup>&</sup>lt;sup>h</sup> Solanum nigrum Lin. Curtis, Lond. II. 14. Engl. Bot. 566.

i Solanum tuberosum Lin. Fl. Rust. 139. The English name is evidently a corruption of the Indian Batass.

Solanum Lycoperficum Lin. Blackw. 133.

found. This has an unarmed herbaceous stem, which is very hairy; the leaves also are pinnate, but cut; and the flowers are borne on simple unbranched bunches; the corolla is yellow, and the fruit or berry is

large, flatted, and deeply furrowed.

Melongena or Mad Apple1 is also of this genus; it is cultivated as a curiofity for the Jargeness and shape of its fruit; and when this is white, it has the name of Egg Plant; and indeed it then perfectly refembles a hen's egg in fize, shape, and colour. The stem of this is herbaceous, and without. prickles; the leaves ovate and nappy; the peduncles pendulous, and growing thicker towards the top, and the calyxes unarmed. The corollas are purple, and the fruit varies much in colour. The three last species recede a little from the character of the order; for the potato and tomatos have many cells to the fruit, and this has but one.

The prickly forts of Solanum are natives of hot countries, and most of them are brought to us from the Spanish West Indies: they will not therefore commonly fall under your observation.

Capsicum, or Guinea Pepper, is also of this lurid order; its beauty and use lie in the fruit, which Linnæus calls a dry or juiceless berry, and others a capsule or pod.

<sup>&</sup>lt;sup>1</sup> Solanum Melong and Lin. Pluk. phyt. t. 226. f. 2. This

This circumstance together with the rotate form of the corolla, and the anthers being connivent or converging, make up the efsential characters of the genus. Linnæus has only five species, one annual with an herbaceous stem, the rest perennial with woody stems n. Others make many more species from the different form of the fruit: which indeed varies much both in shape and colour, and, intermixt with the white flowers and green leaves, makes a pleafing variety: but Linnæus does not allow the form of the fruit in this genus to be permanent enough to constitute specific differences. They are all very hot, and hence have the names of bell pepper, ben pepper, barberry pepper, and bird pepper. The bell pepper, which has large, swelling, wrinkled fruit, with a fleshy tender skin, of a red colour when ripe, is the only fort fit for pickling. Cayan pepper is made from the last, whose fruit is small, oval, and of a bright red, and much more pungent than the rest. Most forts of capsicum come from both East and West Indies. Though they are used in hot countries so universally with their food, yet the ripe fruits thrown on the fire will emit strong noisome vapours, which occasion violent sneezing, coughing, and often vomiting, in those

m Capsicum annuum. Blackw. 129.

<sup>&</sup>quot; Capficum baccatum, finense, groffum & frutescens.

who are near; and mixt in fnuff will have the same effects to a violent and dangerous degree: so that these plants, though not strictly poisonous, are however worthy a

place in the lurid tribe.

Lonicera In this first order of the fifth class are to be found feveral well-known shrubs, among which the boney-suckle is eminent. Of these the Italian° and Wildp species are the principal. They are distinguished by the first having the upper pairs of leaves connate, or fo joined as to form but one, and the stalk running through the middle of them: whereas in the wild honey-fuckle they are all diftinct. The Dutch or German honey-fuckle of the gardens is supposed to be a variety only of this, though it is much stronger, and not so apt to climb. The woodbine has indeed very flender trailing branches, twining round the boughs of trees, and climbing to the very tops of them.

Trumpet honey-fuckle<sup>4</sup> is a North American; it agrees with the Italian in having the upper leaves connate; with the wood-bind in its flender trailing branches: but differs from both in the whorls of flowers being naked or void of leaves, and the corollas being almost regular; the leaves also

o Lonicera Caprifolium Linnai Hort. Angl. t. 5. Pl. 12. f. 4.

P Lonicera Periclymenum Lin. Woodbind. Curtis, Lond. I. 15.

Lonicera sempervirens Lin. Riv. mon. 116.

are evergreen, and the corollas are bright scarlet on the outside, and yellow within.

There are other species, which you will find among the shrubs, differing in appearance, and receding fomething in character from honey-fuckles properly fo called. These have always two flowers only coming out together; whereas in the former the flowers grow in whorls or heads many together. Fly honey-fuckler has the two berries that fucceed the two neighbouring flowers distinct; the leaves are entire and hoary; and the corollas are white. Redberried upright honey-fuckles has the two berries joined together; the leaves lanceshaped and smooth; the corollas are red on the outside, but pale within. This is not fo tall-growing a plant as the other.

The five recited species agree in having a monopetalous irregular corolla, except that in the trumpet honey-suckle it is almost regular; in the genuine honey-suckles the tube is remarkably long. The seed-vessel in all is a berry growing below the slower, and inclosing several seeds; though the last

has only two.

taining twenty-seven species, is also of the first order in the class *Pentandria*: these are either thorny, prickly, or unarmed. Buck-

· Lonicera alpigena Lin. Mill. fig. 167. 2.

Lonicera Xylosteum Lin. Mill. fig. 167. 1.

thorn is one of the first; having thorns terminating the branches, the stem erect. the leaves ovate, and the calvx cut into four fegments: the berries have four feeds in them, and, if you wet them and rub them on white paper, they will stain it of a green colour. I mention these two circumstances, because they who gather the berries for sale are apt to mix others with them: and I know you will be interested in them, when I inform you, that the fine green colour" which you use in your miniature painting is made from these berries. If you should have the curiofity to fearch the hedges for them, in order to make this paint yourfelf, you must not be surprised if you do not find them on every buckthorn shrub; for all the flowers are incomplete, some plants having them with stamens, others with a pistil only; and the former of these are never succeeded by fruit.

Berry-bearing Alder is one of the unarmed species. It grows in woods, is a black looking shrub, with bunches of inconsiderable herbaceous flowers, with a quinquesid corolla, succeeded by black berries containing four seeds: the leaves are

ovate, smooth, and quite entire.

t Rhamnus catharticus *Lin*. Fl. Dan. \$50. Duham. 50. Ger. 1337.

v Rhamnus Frangula Lin. Fl. Dan. 278. Duham. 100. Ger. 1470. Engl. Bot. 250.

Another

Another of the unarmed division is the Alaternus", formerly so shorn and beclipped in hedges and covering of walls, but now feen chiefly among other evergreens, taking its natural form. The leaves are extremely shining, generally notched or ferrate about the edges: the flowers have a trifid stigma, and are incomplete, like those of the buckthorn: the corolla is quinquefid, and the berry has three feeds. There are feveral varieties of Alaternus, differing in the shape of the leaves and depth of the serratures; they are also sometimes blotched or variegated. This shrub is frequently confounded with Philyrea, from which it may be known at all times by the position of the leaves, which is alternate in this, and opposite in that: when the two shrubs are in flower, you perceive other more essential distinctions.

Paliurus, or Christ's-Thorn's, is one of the prickly division. It has double prickles, the under ones reflex, and is another instance of irregularity in this genus, the germ being trilocular, surrounded by a membranaceous rim, and crowned by three styles. It has a pliant weak stem requiring some support; the flowers grow in clusters, and are of a greenish yellow colour: the corollas are quinquesid. Being very common in Palestine, it is supposed to be the thorn with which our Saviour was crowned.

w Rhamnus Alaternus Lin. \* Rhamnus Paliurus Lin.
The

The common character of all these is, that there is only a calyx or corolla, with five small scales, one at the base of each division, bending towards one another, and defending the stamens; the seed-vessel a roundish berry, divided within into sewer parts than the corolla or calyx.

Currants and goofeberries, the ivy and the vine, are also of this order Monogynia; but, being so well known to you and every body, I will not dwell on them, having already run out this letter to so great a

length.

Some other trees and shrubs are less known, because they are the growth of hotter climes. Such is the coffeeb, originally of Arabia, though now common in both the Indies. It is known by its falvershaped corolla, with the stamens growing upon the tube of it; and by its feed veffel, which is a berry below the flower, containing two feeds covered with an aril, or detached coat. This tree does not grow above fixteen or eighteen feet high; the leaves are large, of a lucid green, lance-shaped, and waving about the edges. The flowers are produced in clusters, close to the branches; the corollas are quinquefid, of a pure white colour, and a very grateful odour. It is an evergreen, and at all times makes a beautiful appearance.

Cestrum

Y Ribes Linnai. Toll Ol D.

<sup>&</sup>lt;sup>2</sup> Hedera Helix Lin.

<sup>&</sup>lt;sup>2</sup> Vitiș vinifera Lin.

b Coffea Arabica Linnæi. Blackw. 337. Dougl Bradl. et Ellis monogr.

Cestrum or Bastard Jasmine is a shrub of Cestrum. the West Indies, and therefore requires a stove to keep it alive in these northern countries. It has a sunnel-shaped corolla; the silaments have a little process in the middle; and the seed-vessel is an unilocular berry, containing several seeds. One species has clusters of herbaceous slowers on short peduncles, smelling sweetly in the night. And another, with leaves of a lively green, and great consistence, has clusters of white slowers sitting close to the stalk, smelling sweet in the day time.

Dio/ma is a genus of shrubs from the Cape Diosma. of Good Hope. These are of another phalanx, having five petals to the corolla, which is inferior, or incloses the seed-vessel. The germ also is crowned with five nectaries, and becomes three or five united capsules, containing each one seed, with an elastic Aril involving it. The slowers are small, but elegant; white, and of an agreeable spicy odour.

Other foreign trees and shrubs of this class and order are, the Iron-wood tree, the Phylicas, the Mango-tree, and some others: but since it is not probable that you will meet with these, I have not troubled you with their characters, or any account of them.

Cestrum nocturnum Lin. Dill. elth. t. 153. f. 185.

d Cestrum diurnum Lin. Dill. elth. t. 154. f. 186.

<sup>\*</sup> Sideroxylon.

Mangifera Indica Lin.

Phlox.

There remains some specious plants to be noticed, which are commonly cultivated in slower gardens for their beauty. Such are all the species of Lychnideas: which you will know by their salver-shaped corolla, with a bent tube; their silaments of unequal length; their trissid stigma; their prismatic calyx; their three-celled capsule, with one seed in each cell. They are perennial plants; the corollas of most of the species are large, and of a purple colour; and the leaves are lance-shaped. They are the produce of North America.

Upon the first discovery of the New World, as America was vauntingly called, every thing found there was represented as

wonderful. Strange stories were related of the plants and animals they met with, and those which were sent to Europe had pompous names given them. One of these is Mirabilis the Marvel of Peru, the only wonder of which is the variety of colours in the slower. It appertains to this class and order, and has the following generic marks—the corolla is funnel-shaped, the stigma globose; and there is a globose nectary inclosing the germ, which afterwards hardens to a kind of nut. There are three species: first, the common Marvel of Peruh, which has so

much

g Phlox Linnai. See Mill. fig. 205. and Curt. Magaz. 163. 411. 415.

Mirabilis Jalapa Lin. Blackw. t. 404. Curt. Magaz. 371.

much variety of colour in the flowers of the same plant: these are produced plentifully at the ends of the branches, and in hot weather do not open till towards evening; but when it is cool covered weather, continue open the greatest part of the day. Secondly, that whose root was supposed, though erroneously, to yield the jalapi; the stalks of this are swollen at the joints, the leaves are smaller, and the flowers fit singly close in the axils of the leaves; they are not variable, but all of a purplish red, and not much more than half the fize of the others: the fruit also is very rough. In the West Indian Islands, where it is very common, they call it four o'clock flower. Thirdly, the long-flowered Marvel of Peruk, whose corollas are white, and have remarkably long tubes; they have a musky odour, and keep close shut all the day, expanding as the sun declines: they grow in bunches like the first fort, and the feeds are rough like the fecond: this differs from both the others in having weak stalks that require some support; and these, with the leaves, are hairy and viscous. This species is from Mexico, and has not been long known.

The Crested Amaranth belongs also to this Celosia. place; it is commonly called Cock's comb, from the form in which the head of flowers grows. It ranges in the division of incom-

i Mirabilis dichotoma Lin. Mart, cent. t. 1.

<sup>\*</sup> Mirabilis longistora Lin.

plete, inferior flowers: and the generic characters are—that the exterior calyx confifts of three dry coloured leaves, within which is a corolla or fecond calyx, confifting of five stiff sharp-pointed leaves; that there is a small rim surrounding the germ, from which the slaments take their rise; and that the seed-vessel is a round capsule, opening horizontally, and containing three seeds.

There are many species; but that which is so much esteemed for the variety of form and colours in its fine crest of slowers, is distinguished by oblong ovate leaves, round striated peduncles, and oblong spikes. The colours are red, purple, yellow, white, and variegated; and some are like a fine plume of scarlet feathers. You must not, however, consound these plants with the Amaranth or Prince's Feather, which you will find in a place far distant from this.

One natural order more shall, if you please, conclude your labours, and my prate, for the present. It has its name from this circumstance: the divisions of the corolla are turned or bent in the same direction with the apparent motion of the sun. But, besides this singularity, the slowers of this order have a one-leased calyx divided into five segments; a corolla of one petal; and

<sup>1</sup> Celosia cristata Lin. m Contortæ Lin.

a fruit confishing of two vessels, containing many seeds. In most of the genera these fruits are follicles. The corollas in the greater part are funnel-shaped, and are furnished with a remarkable nestary.

The common Periwincle, which covers Vinca. the ground, and creeps about the bottoms of the hedges, in many parts of your plantations, may ferve you very well for an example of this order. It has a falver-shaped corolla, succeeded by two erect follicles, which contain feeds that are called naked or simple, to distinguish them from those of some other genera which are winged. You will observe also that the tube of the corolla forms a pentagon, at top; nor will it escape you, that there are two large stigmas, one over the other.

Linnæus will not allow that the little running fort, and the upright one with larger flowers, are distinct species. Without entering into any controversy on a matter not easy to settle, you know them asunder not only by their size, but by the stalks of the first lying on the ground, and the leaves being narrower, and sharp-pointed towards either end, that is lance-shaped,

and

This is a dry feed-veffel, of one cell and one valve; the feeds lie loofe in a down, and the shell opens on one side to let them escape.

º Vinca minor Lin. Curtis, Lond. III. 16.

P Vinca major Lin. Curtis, Lond. IV. 19. Pl. 12. f. 5. Engl. Bot. 514.

and on very short petioles; whereas the stalks of the second are upright, and will clumb a little, and the leaves are hollow at the base, and ovate, sharper pointed at the

end, and oh longer petioles.

There is a third fort, called Upright Periwincle, for which we are obliged to the Island of Madagascar, and of course it requires the protection of a stove in our colder climates. It has a stiff, upright, branching stalk, woody at bottom; the leaves are of an oblong ovate shape, smooth and succulent, and fitting pretty close to the branches; from the axils of these come out the flowers. on very short peduncles, generally fingle, but fometimes two together: the tube of the corolla is long and slender, the brim very flat, the upper service of a bright crimson or peach colour; the under of a pale fieth colour: and there is a constant succession of these beautiful flowers from February to October: the corolla is fometimes white.

Nerium.

The Oleander r is one of the most beautiful plants of this tribe. The genus has two erect follicles, like the last; but the seeds inclosed in them are downy: there is a short crown also terminating the tube of the corolla cut into narrow segments, and the divisions of the corolla are oblique to the tube. This shrub grows to the height of eight or ten feet; the branches come out

Vinca rosea Lin. Mill. fig. 186. Curt. Magaz. 248°
 Nerium Oleander Lin. Figured in Miller's Illustr.

by threes from the main ftem; and the leaves also come out by threes from the branches, on very short petioles, point upwards, are very stiff, and end in sharp points. The flowers come out in bunches at the ends of the branches: the corolla is of a bright purple, varying to crimfon or white. It grows wild in feveral countries about the Mediterranean Sea, but with us is generally kept in tubs, not being hardy enough to ful-

tain the feverity of all our winters.

But the most admired of this tribe is the Gardenia Cape Jasmine', which was first discovered near the Cape of Good Hope by the superior fragrancy of its flowers. The divisions of the calyx are uniform and vertical, and the feed-vessel is a two or four-celled berry, below the flower. The branches come out by pairs, and the leaves are opposite, close to the branches, of a shining green, and thick confishence; the flowers are produced at the ends of the branches; the corolla is of one petal only, but cut into many fegments, of which it has fometimes three or four rows, and then it is as large and as double as a rose: the anthers are inserted on the tube without filaments. The colour of the coralla is white, changing as it decays to a buff-colour; and the odour is that of Orange-flowers or Narcissus.

There is another plant of this order of Plumeria

<sup>\*</sup> Gardenia florida Lin. Mill. fig. 180. twifted

twisted corollas, called also a Jasmine, with the addition of Red, but of a very different genus from the Jaimines properly fo called. Plumeria or Red Jasmine has two reflex follicles, with the feeds flat, winged, and imbricate. There are four or five known species, all natives of the Spanish West Indies, except one, which comes from Senegal. The fort most known ' has oblong ovate leaves, with two glands upon the petioles: it grows to the height of eighteen or twenty feet; the stalks abound with a milky juice, and towards the top put out a few thick fucculent branches; at the end of which come out the flowers in clusters, shaped like those of the Oleander; of a pale red colour, and having an agreeable odour. These being never succeeded by the fruit in our northern climes, you will not be able to difcern the generic character.

The famous Jesuit's Bark is from a tree of this class and order", approaching in its characters to the natural tribe of Contorta: to which also belong some plants of the fecond order of this fifth class, because they have two pistils: such are the Periplecas, the Cynanchums, and the numerous genus Asclepias of Asclepias, containing twenty-leven species. Of this last, you have the common Swallow-

t Plumeria rubra Lin. Catesb. car. 2. 92. Ehret. t. 10. Curt. Magaz. 279.

<sup>12</sup> Cinchona officinalis Lin.

wort, or Tame poison, whose root is supposed to be a powerful antidote to poisons: it has a short upright stalk, ovate leaves bearded at the base, white flowers growing in proliferous umbels\*, and each of themfucceeded by two long, jointed follicles inclosing feveral compressed feeds, crowned with a foft white down. This is a native of the fouthern countries of Europe, and is very hardy. Other species are much larger, growing to the height of fix or feven feet. Some creep very much at the root, and become troublesome in a garden. Others coming from the Cape, or the warm parts of America, require care and heat to preserve them. Some have white, others purple, orange, or red corollas. Some have the leaves opposite; others have them alternate; in some again they are flat, whilst others have their edges rolled back. Many of the forts are very handsome. They all agree in the following circumstances, which therefore form the generic character-that the fegments of the corolla are bent back; that five ovate, hollow nectaries, ending at bottom in a sharp spur, involve the stamens and pistils; and that each flower is succeeded by two follicles inclosing many downy seeds.

Stapelia is so remarkable a plant of this Stapelia. tribe, that I must not omit mentioning it.

v Asclepias Vincetoxicum Lin. Fl. Dan. 849.

w That is, the large umbels have smaller ones issuing from them.

This has a very large wheel-shaped corolla, divided beyond the middle into five segments, which are broad, flat, and sharp-pointed. The nectary is a double star, one of them surrounding, the other covering the stamens and pistils. Two follicles, inclosing many slat, downy seeds, follow each flower,

There are three known species, all growing naturally at the Cape of Good Hope, and all having succulent branches, as thick at least as a man's finger. The three forts are distinguished by the indentures on the sides of these leastless branches; which in the first spread open horizontally, ending in acute points; in the secondy have their points erect; and in the third obtuse.

In the first species the flowers come out fingly on a short peduncle from the side of the branches towards the bottom; the corolla is greenish on the outside, but yellow within, having a purple circle round the nectaries, and the whole is finely spotted with purple, like a frog's belly. The branches of the second fort are much larger, and stand more erect: they have four longitudinal surrows, and the indentures are on the ridges between them. The slowers are much bigger than those of the last, of a

<sup>\*</sup> Stapelia variegata Lin. Bradl. succ. 3. t. 22. Curtis's Mag. 26.

y Stapelia hirsuta Lin. Mill. fig. 258.

<sup>&</sup>lt;sup>2</sup> Stapelia mammillaris Lin. Burm. afr. t. 11.

thicker substance, and covered with fine purplish hairs: the ground of it is a greenish yellow, streaked and chequered with purplish lines.

This genus has lately received a great accession of new species from the industry of Mr. Masson; who has published a hand-

fome work, with elegant figures.

But the great fingularity of these plants is that the flower when fully open has a setid smell so perfectly resembling that of carrion, that the common sless-fly deposits her eggs in it, which frequently are hatched into little worms, but never proceed any farther, or become slies. A rare instance this of an animal mistaking its instinct.

Having by this time fufficiently fatigued you, I leave you, dear cousin, to meditate on this irregularity in the operations of Nature, and once more heartily bid you adieu.

## LETTER XVII.

ON THE OTHER ORDERS OF THE FIFTH CLASS, PENTANDRIA, DIGYNIA, &c.

May the 1st, 1774.

AM not furprised, dear cousin, at your being solicitous to know what the nectary is, which I mentioned several times in my last. But I am not disposed at present to satisfy your curiosity any farther, than to inform you, that it is an appendage to the corolla, and that there is a juice in it, probably of use to the plant, certainly serving for the food of bees, and numberless other insects. It is a perfect Proteus, and puts on a far greater variety of forms than the son of Neptune. Another time I may perhaps enter more deeply into this matter; but at present we will go straight on our way.

You will have great pleasure when I inform you, that the second order of the fifth class a is almost wholly made up of the Umbellate tribe of plants, which you are already to well acquainted with: there are however some, which the circumstances of having five stamens and two pistils bring into the same division of the arbitrary system, though they are not naturally related

a Pentandria Digynia Lin.

to them. A few of these we will examine, before we enter into a detail of the *Umbellate* tribe.

Many of them have incomplete flowers, or are deficient in the corolla; and may be found among the *Oleraceous* plants in the natural orders of Linnæus, by other authors called *Apetalous*.

Such are all the Goosefoots, of which there Chenoare no less than twenty species, most of podium. them growing common on dunghills, and in waste places, and having no beauty to attract your notice. They are known by their five-leaved, five-cornered calyx, inclosing one round, flattish seed, shaped like a lens. One of the most respectable species is the English Mercury or Allgood', growing frequently in waste places, and by walls and way-fides, and cultivated in some places as a substitute to Spinach. The leaves of this are triangular, quite entire, waving, and have the under furface covered with a kind of meal; the flowers grow in compound spikes, which are destitute of leaves, and fpring from the axils.

Beet is very nearly allied to these in its Beta. characters; but it is distinguished by having a kidney-shaped seed, wrapped up in the substance of the calyx. In its wild state, on the sea-coast, and in salt marshes,

<sup>&</sup>lt;sup>c</sup> Chenopodium Bonus Henricus Lin. Curtis, Lond. III. 17. Ger. 32.

d Beta maritima Lin. Engl. Bot. 285.

Salfola.

it has two flowers coming out together; the stalks are weak, and lie mostly on the ground; the leaves are triangular and oblique or vertical; the divisions of the calyx are equal and not toothed at bottom, and it showers the first year of its rising from seed. The garden fort has many flowers coming out together, the stalks erect, the leaves oblong, lance-shaped, thick, and succulent; the divisions of the calyx are toothed at the base, and it does not flower till the second year.

It fometimes has pale green leaves, and fmall roots; fometimes dark red, or purple leaves, with large purple roots shaped like a carrot; but these are not generally supposed

to be distinct species.

The Glassworts are also of this Oleraceous tribe. They are distinguished by having a large seed, spiral like a screw, covered with a kind of capsule which is wrapped up in the calyx. There is one sort that grows wild in the salt marshes, which has an herbaceous stalk that lies on the ground; awl-shaped, rough leaves terminating in spines; the calyxes edged, and sitting close in the axils, and a trifid style.

Another fort, which grows wild in warmer countries, has also herbaceous

fpreading.

<sup>·</sup> Beta vulgaris Lin.

f Salfola Kali *Lin.* Fl. Dan. 818. Mor. Hift. 3. 5. t. 33. f. 11. Engl. Bot. 634.

<sup>8</sup> Salsola Soda Lin. Jacq. Hort. t. 68.

fpreading stems; but it is a much larger plant than the other, and the leaves have no spines. These or any of the sorts yield the caustic alkaline salt, which is so necessary in that most elegant and useful manufacture of glass; but this is the sort ge-

nerally used.

The Globe Amaranth is of this class and Gomorder. Its fine round head is composed of phrena. many flowers which have a large, boatshaped, flat, coloured calyx, of two leaves; a corolla divided into five rude, villous fegments; a cylindric nectary, divided into five parts at top; a style cut half way into two; and a capfule opening horizontally, and containing one feed. India is its native country; the stalk is erect and annual; the leaves are lance-shaped, as are the branches and peduncles, which are long and naked, except that a pair of short leaves grows close under each head of flowers, which always comes out fingle. The calyx and corolla, being dry and chaffy, will retain their colour feveral years, and hence their name of Amaranth or incorruptible. Bright purple is the usual colour, but sometimes the heads are brilliant white, or filver-coloured. The name must not lead you to fuppose this, any more than the crested Amaranth, to be of the same kind with the true Amaranthi.

See Letter XXVIII.

h Gomphrena globofa Lin. Mill. fig. pl. 21.

Ulmus. When you are told that the Elm is of the fame class and order, and also one of the incomplete tribe, as having no corolla, you will probably reflect that an artificial system is very different from a natural arrangement: and in this you are not mistaken; but then you must consider that an artificial system is the only one that can enable you to find out the genera and species of plants, which is the art I propose to instruct you in. Few perfons know that the Elm has any flower, because it is inconsiderable in size and appearance, and comes out in an early inclement feafon: however, this tree in reality abounds in flowers, before the leaves make their appearance. They have no corolla, but a quinquefid calyx: the flower quickly passes, and is succeeded by one seed covered and furrounded by a flat membrane. The different forts, known by the names of Rough Witch Elm, Smooth-leaved Witch Elm, Witch Hazel, English Elm, Dutch Elm, Upright Elm, &c. are supposed to be varieties of one speciesk; and all have doubly-ferrated leaves, unequal at the base.

Gentiana The Gentians are also of this class and order, and of that subdivision which has monopetalous inferior corollas. They are distinguished from the other genera of this fubdivision by the capfule, which is oblong, round, and sharp-pointed; has one

cell,

L' Ulmus campestris Lin. Duham. t. 108. Hunter's Evel. Silva, p. 114.

cell, opens by two valves; and has two receptacles on the infide, each adhering lengthwise to one of the valves. The form of the fruit is constant; whereas the figure and number of parts in the flower vary in the different species, which are numerous. Great part of the skill and sagacity of the botanist consists in seizing those parts which are constant in all the species, for the generic characters, and in this consists the great merit of Linnæus; writers before him having either taken all parts indiscriminately, or else the same part invariably for this purpose.

The species have either four or five petals, and the latter have either funnelshaped corollas, or else approaching to bellshaped; hence a three-fold division of the

genus.

The principal of the genus is the Great Yellow Gentian m, which has a fingle stalk, three feet high, covered with leaves that are large, ovate, marked underneath with nerves meeting at the tip; the lower ones petiolate, the upper sessible. There is but one flower to a peduncle, but they grow round the stalk in whorls: the calyx refembles a double spathe: the corolla is rotate, cut into five segments the colour yellow irregularly dotted. The root is very

<sup>1</sup> Thirty-nine.

m Gentiana lutea Lin. Mill. fig. 139. 2.

<sup>&</sup>quot; Varying sometimes as far as eight.

large, and remarkably bitter; it communicates the bitterness so much to the whole plant, that it remains always untouched by the cattle in the mountainous pastures of Germany and Switzerland, where it grows

naturally.

The Leffer Centaury is of this genus, and is distinguished by its dichotomous stalk, and its funnel-shaped corollas divided into five segments: they are of a bright purple colour, but often sade to white. This plant is annual, and varies much in height according to the soil, from three or sour inches to a soot. This is extremely bitter as well as the other.

There are feveral beautiful little Gentians, with flowers of the finest blue that can be imagined, growing wild in the Alps. One of them is frequently cultivated in gardens, under the name of Gentianella, and is singular for having its sine bell-shaped azure flowers larger than the whole plant besides.

Chlora.

Yellow Centaury q is also naturally of this genus; but has been removed to the eighth class; first with the title of Blackstonia, and now under that of Chlora.

But methinks you are languishing to be

Chlora perfoliata Lin. See Letter XIX.

Gentiana Centaurium Lin. Chironia Centaurium, Curtis, Lond. IV. 22.

P Gentiana Acaulis Lin. Jacquin austr. 2. t. 135. Curt. Magaz. 52.

on ground you are better acquainted with. And indeed you are already fo well versed in the nature of the umbellate tribe, that I am persuaded you will find little difficulty in determining the genera and species. Many of them are very generally known, either for their use in medicine or the kitchen, or else for their poisonous qualities. Most of those which grow on dry soils have roots that have an aromatic pungent smell and taste; whilst those which grow in moist places or in the water, as many of them do, are in a greater or less degree poisonous.

You have long since been able to distin-Scandix. guish true Parsley and Chervil from Fool's Parsley. There is another wild plant that grows upon banks and by way-sides, called Hemlock Chervil, which has been mistaken for Garden-Chervil, and has produced bad effects when put into soups: it is not however so dangerous, because it does not grow wild in gardens, and we must go out of our way to poison ourselves: on another account however it is more dangerous, because it is not only of the same division, as having partial involucres only, but also of the same genus; and therefore

liable to be mistaken for the true Chervil,

<sup>\*</sup> See Letter V.

Scandix Anthriscus Lin. Curtis, Lond. I. 19. Fl. Rust. t. 75.

<sup>&</sup>lt;sup>t</sup> Scandix Cerefolium Lin. Jacquin austr. 4. t. 390. Compare Pl. 13. f. 2. & Pl. 5. f. 3.

even when in flower, which Fool's-Parsley cannot be. They have both a radiate corolla, petals notched at the end, the flowers in the middle often incomplete and producing no feed, and the fruits of an oblong shape. However, notwithstanding all this fimilitude of character, they are easily to be distinguished both in and out of flower. Hemlock-Chervil is a much lower plant; the stalks are smooth indeed, and the leaves finely cut, but they are hairy, the divisions much fmaller and closely placed, and the green much deeper than in Garden-Chervil; the corollas also are uniform, the feeds ovate, and very rough. Garden-Chervil is a tall, genteel, smooth plant; the umbels come out on the fides of the branches, and fit close to them; and the feeds are long, narrow, and shining. After all, I am perfuaded that when you have an opportunity of comparing these two plants together, as you easily may, the gardener furnishing you with one, and the other being fo common in a wild state, you will wonder that any person should ever have confounded them. Here you fee we have an instance of an umbellate plant growing on dry land that is poisonous; you are not therefore to conclude that all these are wholesome, any more than that every water species is poisonous.

Sium.

We have another instance of fatal confufion, not in two plants of this tribe, but in one of this with another of a different class; namely,

namely, of the Creeping Water Parsnep" with Water Cress, which belongs to the cruciform flowers. You are so well mistress of both tribes, that it is impossible you should mistake them when in flower; but this is not the time when Water-Creffes are eaten, and this plant is so different in its flowering state, that I am persuaded an eater of it would think himself imposed upon, if he were then shewn it for Water-Cresses. When they are both young they are really not unlike; and fince they frequently grow together, the one may fometimes be gathered for the other; though I must confess that I have not met with the mistake more than twice, and that only in a fingle piece among a confiderable quantity: however the leaves of Water Parsnep are of a light green; the small leaves composing the whole winged or pinnate leaf are longer and narrower, ferrated on the edges, and pointed at the end; whereas those of Water-Cresses have a tincture of brown upon them, the leaflets are roundish, and particularly the odd one at the end is very large and blunt, and they are none of them regularly ferrated, but have only a few indentures on their edges.

Sium nodiflorum Lin. Fl. Dan, t. 247. Mor. Hist. f. 9. t. 5. f. 3. Engl. Bot. 639.

Y Sifymbrium Nasturtium Lin. Fl. Dan. t. 690. Mor. Hist. s. 3. t. 4. f. 8. Ger. 257. 5. Compare Pl. 13. f. 1. with Pl. 21.

The characters by which you will know the Water-Parsnep when in flower are these: -it has both an universal and partial involucre, the flowers are all fertile, the petals are heart-shaped, and the seeds are ovate and streaked. This species is distinguished from the others by its pinnate leaves, and the umbels of flowers fitting close to the stem, in the axils.

Conium. Another poisonous herb of great fame is the Hemlock ": A tall plant, three feet high and more, eafily known by its purplespotted stalk. It has both involucres, the universal of three, four, five, or seven broadish reflexed leaves; the partial of three or four broad leaves only, on one fide of the umbel; both very short. The flowers are all fertile, irregular without, regular within: the petals heart-shaped. The fruit is almost spherical, marked with five notched ridges. The common species is distinguished by its smooth streaked seeds. The leaves are large, abundant, of a dark green but shining, triply pinnate, with the last divisions obtufely indented; it has many umbels of white flowers, with numerous spreading rays. It grows wild on ditch banks, in shady lanes, about dunghills and church-yards; and is a biennal plant.

The waters afford other poisonous herbs,

<sup>&</sup>quot; Conium maculatum Lin. Curtis, Lond. I. 17. Ger. 1061.

as Water-Hemlock\*, Long-leaved Water-Hemlock\*, Hemlock Water Dropwort\*, and Common Water Dropwort\*: but let us quit these ill-omened plants, and proceed to others more innocent, and more within your reach.

Two umbeliate plants you will be fure Chæroto find under every hedge, called Wild Cher- Phyllum vilb and Rough Chervilc: they are both of the same genus, but of a different genus from Garden Chervil. They have partial, but no universal involucres: these are of five leaves, concave and bent back; fome flowers in the middle drop without leaving feeds; the petals are bent in and heartshaped; and the fruit is oblong and smooth. The first, vulgarly called Cow-weed or Cowparfley, has a smooth streaked italk, and the joints swelling but a little. The second has a rough stalk, and the joints more tumid. The first is remarkably leafy, and the leaves very large, and generally smooth, except the nerves. The second has hairy

<sup>\*</sup> Phellandrium aquaticum *Lin*. Mor. Hift. f. 9. t. 7. f. 7. Ger. 1063. 2. Engl. Bot. 684.

<sup>&</sup>lt;sup>a</sup> Oenanthe fiftulosa *Lin*, Fl. Dan. 846. Mor. Hist. f. g. t. 7. f. 8. Ger. 1060. Engl. Bot. 363.

b Chærophyllum sylvestre Lin. Curtis, Lond. IV.

<sup>25.</sup> Mor. Hift. t. 11. f. 5. Fl. Ruft. t. 96.

Chærophyllum temulum Lin. Curt. Lond. n. 61.

Mor. Hift. t. 10. f. 7. Ger. 1038. 2.

leaves, not so large, nor so much divided: the umbels usually nod, and the feeds are deeply streaked. Both sometimes have a leaf at the origin of the universal umbel: both have a strong smell, and approach in their qualities to the forementioned plants, but not enough to denominate them poifonous.

Some of this tribe are fo generally used in

food, that they are univerfally known, and therefore it feems impertinent to fay any thing to you about them; and yet you may have eaten the roots of Carrots and Parsneps, the stalks of Angelica, Celeri, and Finochia, the leaves of Parsley, Fennel, and Sampire, the feeds of Coriander and Carraways, without knowing one of the plants when they are presented to you. However, when you meet with any of these in flower, you ascribe them immediately to the umbellate tribe. Carrot, Sampire, and Angelica, range among those which have both involucres; Coriander has a partial involucre only; and the rest have neither one nor the other. Daucus. Carrot d has a large winged involucre: fome flowers in the middle drop without feed, and the fruit is stiff with bristles. The outer flowers are very irregular: and the whole umbel, as it approaches a state of maturity, takes a hollow form, very like a bird's nest.

The

d Daucus Carota Lin. In the cultivated fort all the flowers are fertile. Fl. Dan. 723. Mor. umb. t. 2. Ger. 1028. Fl. Rust, t. 82.

The leaves are rough and hairy. The garden Carrot differs little from the wild one, but in the fize and tenderness of the root.

Sampire has the umbel not flat, or hol- Crithlow like the last, but hemispherical, the mum. flowers all alike and fertile, the petals flat, the fruit ovate, flatted. The stalks are succulent, the leaves pinnate, composed of three or five divisions, each of which has three or five small; thick, lance-shaped leaves; the corollas are yellow. This herb strikes its roots deep into the crevices of the rocks, and hangs down: growing chiefly in places difficult of access, the herb-gatherers are tempted to substitute another plant f, which they obtain without trouble on the beach, but which has none of the warm, aromatic quality of the Sampire. Those who live on the east coast must wonder what is meant by calling the occupation of a Sampire-gatherer, dangerous trade, when they obtain it walking at their ease on the flat sandy shore. But theirs is a roundish, jointed, tasteless stalk, with a tough string running through the middle of it 5, instead of a flat leaf, with a pungent taste. This Marsh Sampire ranges in the first order of the first class, and is burnt to make kelp for the glass-works.

<sup>&</sup>lt;sup>e</sup> Crithmum maritimum Lin. Jacqu. hort. 2. 187. Ger. 533. 1.

Inula crithmoides Lin. Golden Sampire.

Salicornia europæa Lin. Marth Sampire, called also Jointed Glasswort or Saltwort. Fl. Dan. 303. Blackw. 598.

Here you fee what confusion of names we have again, and how difficult it must be to obtain the plant you want, without knowing something more of it than the name. It is generally true of objects much in request, that where people have them not, they substitute others, to which they give the same title, whether they have the same qualities or not; by which, if they do not injure themselves or their neighbours, they at least mislead the incautious and unexperienced naturalist.

Angelica

Angelica has large globose umbels, all the flowers in them are regular and fertile, the petals are inflex, or bent upwards at the end; the fruit is roundish, cornered, or furrowed, and terminated with two reflex styles.

The cultivated h and wild i Angelica are allowed on all hands to be distinct species. They have both pinnate leaves; but the first has the odd lobe at the end divided generally into three parts; the second has all the leaslets equal, lance-shaped, and servated about the edges. The first is a much larger plant in all respects, the leaslets broader, rather ovate than lance-shaped, and the corollas greenish: the second has a thinner and less succulent stem, scarcely any universal involucre, and the corollas tinged with red.

Angelica sylvestris Lin. Mor. Hist. s. 9. t. 3. f. 2. Ger. 999. 2.

h Angelica Archangelica Lin. Fl. Dan. t. 206. Ger. 999. 1.

Coriander k has no proper universal invo-Corianlucre, though there be sometimes one leaf, drum.
as in the Wild Angelica; the partial one
consists of three leaves, and is thort. The
slowers in the middle produce no seed; the
petals are bent inwards, and heart-shaped;
the outer ones large. The fruit is spherical, as you know. The calyx of each
little slower is more evident in this than in
the other umbellate plants. The divisions
of the leaves next the ground are broad;
those of the upper ones narrow: they and
the whole plant are smooth, and have a
strong rank smell, like bugs.

Parsnep<sup>1</sup> has all the flowers fertile and Passinaca regular, the petals entire, and bent inwards; the fruit oblong, flatted, and surrounded with a membrane. The leaves are simply pinnate, the garden Parsnep differs not specifically from the wild, which has hairy leaves, whereas those of the first are smooth; but smoothness is a common effect of culture. The cultivated plant is also of course much larger, and the roots succulent and esculent; both have yellow corollas.

Fennel<sup>m</sup> has likewise all the flowers fer-Anetile and regular; and the petals entire and thum.

bent inwards, as in the last: the fruit is

<sup>&</sup>lt;sup>k</sup> Coriandrum fativum Lin. Blackw. 176. Ger. 1012. Engl. Bot 67. Fl. Ruft. 141.

<sup>&</sup>lt;sup>1</sup> Pastinaca sativa Lin. Ger. 1025. Fl. Rust. t. 83. Engl. Bot. 556

m Anethum Fæniculum Lin. Mill. Illustr. Moris. 1. 9. t. 2. f. 1. Ger. 1032.

nearly ovate, flatted, and streaked. Dill', which is also of this genus, has the fruit surrounded with a membrane, and more flatted than that of Fennel. Sweet Fennel is but a variety of the common fort, though the lobes of the leaves are longer, more slender, and not so dense as in that; the seeds are longer and much sweeter. Finochia is probably another variety, though a much humbler plant, swelling much in breadth and thickness just above the ground. The leaves of all these are very finely cut.

Carum.

Carraway has no proper involucre, but a fingle leaf at the origin of the universal umbel; the middle flowers fall without seed; the petals are keeled, bent inwards, and notched at the end; the seeds are of an

oblong ovate form, and streaked.

Apium.

Parsley and Smallage, or Celoria, are of the same genus. They have a sort of involucre, generally of one leaf; all the flowers fertile; the petals equal, and bent inwards; the fruit small, ovate, and streaked. They have both winged leaves, with the leastlets linear on the stalk in Parsley, wedge-shaped in Smallage, of which Celeri is only an improvement from warmer countries. Our wild Smallage however, which is common

n Anethum graveolens Lin. Ger. 1033:

by ditches and brooks, cannot be rendered

esculent by culture.

Earth nut or Pig-nut, whose roots are Bunium. like a small potatoe and eatable, has both involucres, the lesser ones narrow as a hair; the slowers in a close umbel, all fertile: the corollas regular, with heart-shaped petals; and the fruit ovate. It grows, not uncom-

monly, wild on dry pastures.

Ferulas in the dry stalk of which Prome-Ferula. theus brought fire from heaven, has both involucres; all the slowers fertile, the petals heart-shaped; the fruit oval, slat, and marked with three streaks on each side. It is so losty and large a plant as to have acquired the name of Fennel-gians: the lower leaves spread two seet, and are subdivided into very long, narrow, simple leastlets; the stalk is hollow, jointed, and will grow ten or twelve feet high: when these are dry they have a light dry pith, which readily takes fire; and the people of Sicily use it as tinder. It is a species of Ferula that produces the Assa fætidas.

Cow-Parsnep is a very large plant, though Heraclenot fo gigantic as the last. It has two in-um. volucres; but as they are very apt to drop off, you may easily be deceived in that re-

Bunium Bulbocastanum Lin.: Curtis, Lond. IV. 24. Ger. 1064. 1, 2. There is a smaller and a greater fort.

Ferula communis Lin. Ger. 1056.

<sup>\*</sup> Ferula Assa sætida Lin. Kæmps. amæn. t. 536. \* Heracleum Sphondylium Lin. Mor. Hist. s. 9. t. 16. s. 1. Ger. 1009.

fpect. The corolla is very irregular, bent in and notched. The fruit is ovate, notched, fl tted, streaked, and with a membrane round the edge. In most of the species, the middle flowers fall seedless; but in our common one all the flowers are fertile: the leaves are winged, and the lobes pinnatistid. This plant grows common in meadows and pastures.

Scandix.

Shepherd's needle or Venus's comb' is remarkable for long processes or beaks terminating the seeds, and giving it the appearance of Geranium, when in fruit. It is of the same genus with Chervil, and is a common weed among corn. But of these umbellate plants enough.

Of the third order of this fifth class we have several trees and shrubs; as the Varnish-trees and Sumach, Waysaring-trees and Laurustinus, Cassines, Elder, Bladder-nut, &c. The first are known by their inserior slowers, their five-leaved calyx, their corolla of five petals, and their berry with one

feed in it.

Rhus.

Virginian Sumach w is common among your shrubs, and known to you by the young branches being covered with a velvet-like down, resembling both in colour and texture a stag's horn when first budding:

v Scandix Pecten Lin. Curt. Lond. V. 21. Mor. Hift. f. 9. t. 11. f. 1. Ger. 1040. 1. Pl. 13. f. 3. Fl. Ruft. 38.

w Rhus typhinum Lin. Duhamel.

the branches are crooked and deformed; the leaves are winged, with fix or feven pair of lance-shaped lobes, sharply serrated, and nappy beneath. The slowers are produced in close tusts at the ends of the branches, and are followed by seeds inclosed in purple, woolly, succulent covers, which give them their autumnal hue, when the leaves sade first to purple and then to seuillemort colour.

Way-faring-tree\*, Marsh-elder, and Lau-Viburrustinus, are all of one genus; having su-num. perior flowers, a five-leaved calyx, a corolla divided into five segments, and a berry in-

closing one feed.

The first has heart-shaped leaves very much veined, serrated about the edges, and white underneath. The second has lobed leaves, with glands upon the petioles; the slowers round the outside of the cyme are barren, with the corollas much larger than the others. The Gelder Rose is a remarkable variety of this, with the slowers growing in a ball, and every one of them barren. The third has the leaves ovate, and entire, with the veins underneath villous: this is an ever-green.

The fourth order is a very small one, Parnassia comprising only two genera; of which Par-

<sup>2</sup> Viburnum Tinus Lin. Curt. Magaz. 38.

nassia

<sup>\*</sup> Viburnum Lantana Lin. Duhamel, t. 103. Ger. 1490. Engl. Bot. 331.

massia is one. This grows wild in wet meadows, and on the borders of marshes, but not very common. It is easily known by its calyx divided into five parts; its corolia of five petals; five heart-shaped nectaries, furnished with hairs, upon the top of which are little balls; a large ovate germ, without any style; but four stigmas; and a capsule of one cell and four valves. It has a fingle stalk, with one heart-shaped leaf on it, embracing the stalk, and one slower only; the corolla is white.

Statice.

Of the fifth order, Pentagynia; is Thrift, Flax, &c. Thrift has the calyx of one leaf, entire, plaited, and dry, like chaffe; a corolla of five petals; and one feed crowned with the calyx. These are the characters of the genus, which has twenty-two species. Common Thrift has a threefold involucre or common calyx, and the flowers growing in a round head, upon the top of a naked stalk; the leaves, which form a close tuft near the ground, are linear. The corollas are red, of different shades, from pale flesh colour to bright scarlet; varieties occasioned by soil and situation; for this plant is found both on falt marshes and mountains. Thrift was much used formerly for edging the borders

<sup>&</sup>lt;sup>c</sup> Scariofe.

in flower gardens, but it is now almost entirely out of date.

Flax has also a corolla of six petals; but Linum. the calvx is five-leaved, and the capfule opens by five valves, having ten cells within. in each of which is one feed. There are no less than twenty-two species of Flax: that whose use is so extensived is distinguished from the rest by the calyx and capsule being pointed, the petals being notched, the leaves lance-shaped, and alternate upon the stem. and the stalk unbranched. On the top of this are four or five flowers, with beautiful blue corollas, very apt to fall off. It is an annual plant, about a foot and half high, in the fields. In the garden it will grow fix inches higher, and branch a little where it stands detached.

Both the use and beauty of Flax will interest you; so I leave you with this impression, and bid you once more adieu.

THE CLASS HEXANDRIA.

May the 15th, 1775.

E are returned, dear coufin, to the point from which we first set out; the liliaceous tribe of plants being included in the first order of the fixth class, in the System of Linnaus. These superband beautiful flowers have gained fo much on the esteem of the curious in Europe, that they have spared neither trouble in setching them from the farthest part of the East, nor expence in cultivating them at home. Hence they are fo generally known, that perfons not at all versed in Botany readily find them to be of the same family. You certainly are at no lofs to determine their general relation and analogy, from the hints which were thrown out in the first letter, and the experience you have fince acquired. It remains therefore only to be acquainted with their generic and specific characters; to which end I shall prefent you with some that may be most within your reach: were I to set every liliaceous plant before you, the beauty of which merits your attention, I

See Letter I.

should

should almost exhaust the tribe. Two cautions you are to observe: first, that the whole liliaceous tribe is not confined to the class Hexandrias, though the far greater part of it is; secondly, that other plants, few indeed in numbers, are to be found in the same order.

You remember that the Lily had no calyx; you are not however to suppose that the whole tribe is destitute of this important part of the slower. It is a circumstance that occasions a threefold subdivision of the order, into such as have a calyx or rather a perianth; such as have a spathe or sheath, covering the corolla whilst a bud, but torn and forsaken by the corolla when it is expanded; and lastly, such as have the corolla quite naked.

You would not perhaps have suspected at Bromelia first sight that the Ananas or Pine-Apple is of this tribe. It is almost the only genus capable of misleading you. The flower has a trifid, superior calyx, a corolla of three petals, a scale sastened to the base of each petal; the fruit is a fort of berry. The species h is distinguished by its long, narrow, pointed leaves, like those of Aloes, servated on the edges, and set with tender

f See Letter XIV.

Eighteen genera out of 65. The whole class has eighty-one genera and four hundred and seventy-three species.

Trew. Ehret. t. 2.

fpines; and by the fruit being terminated with a bush of leaves, commonly called the crown, which being planted takes root, and produces another fruit. There are differences in the fruit, proper to be remarked by those who cultivate this luxury; but they are no more than varieties of the same species, and therefore do not concern us as Botanists.

Tradefcantai.

Tradescantia, or Virginian Spiderworti, is another of the liliaceous tribe furnished with a perianth, which in this is three-leaved; the corolla also has three petals, and the capsule has three cells. It is remarkable for having the filaments fringed with purple jointed hairs. The species common in gardens is distinguished from seven others, by its smooth erect stalk, and by the flowers growing in clusters at the top of it. These are of a fine purple, and blow in fuccession most part of the fummer, though each flower continues open but a day. From the number of parts in the fructification, and its ensiform leaves, this plant will range in the fame natural order with Iris and its congenersk.

Galanthus. Of those which have a *spathe* or *sheath* instead of a perianth, there is the modest, the humble, the early *Snow-drop*; that comes

<sup>&</sup>lt;sup>1</sup> Tradescantia Virginica Lin. Mor. Hist. s. 15. t. 2. f. 4. Curt. Magaz. 105. Pl. 14. f. 10.

47. Park. parad. 107. Engl. Bot. 19.

one of the first of the year to salute us, and, no less white than the snow itself, is frequently covered by it. This is distinguished by its superior corolla of six petals, of which the three inner ones are shorter by half than the others, and notched at the end. These are supposed to be the nectary. More needs not to be said of a flower so universally known.

Narcissus is another of this division. Narcissus There are many species, all united by these characters: a superior corolla of six equal petals, and a funnel-shaped nectary, of one piece, within which are the stamens. The most known species are the common white Narcissus, the Dassociila, the Polyanthus Narcissus, and the Jonquile. The first and fecond, in a natural state, have only one flower bursting from the same sheath; the third and fourth have feveral: the first has the nectary or cup in the middle of the flower, wheel-shaped, very short, chaffy, and a little notched at the edge: the fecond has a large, erect, curled, bell-shaped cup q fometimes as long as the ovate petals of the corolla: the third has a bell-shaped,

 N. odorus or Great Jonquil, idem. 78.

<sup>4</sup> Milton has made poetical use of this cup:

<sup>&</sup>quot;And Daffodillies fill their cups with tears'
To firew the laureate hearfe where Lycid lies:"

plaited cup, truncate at the end, and one third of the length of the petals; this has flat leaves, whereas the fourth has them fubulate, long, and narrow, like a rush: this also has a short bell-shaped cup. The esteem in which these flowers have been always held, is the occasion that a great number of beautiful varieties have been produced from the plain simple parents. The Dutch catalogues have no less than thirty varieties of Polvanthus Narcissus: and in the other three the cup is entirely changed into petals by culture. The petals of the first are white, and the cup yellow; the petals of the fecond are naturally pale brimitone, and the cup yellow: the petals of the third are either white or yellow, with orange-coloured cups: and the fourth is all yellow.

Amaryllis. There is no genus of plants in the whole round of vegetable nature more superb in its flowers than the beautiful Amaryllis: known by its superior bell shaped corolla of six petals; its stamens of unequal length; and its trifid stigma. Besides several other species, either less obvious, or less beautiful, you will find here the Jacobea Lily.

Shakespeare informs us of the early appearance of this flower:

<sup>&</sup>quot;The Daffodil
"That comes before the fwallow dares, and takes
"The winds of March."

<sup>&</sup>lt;sup>\*</sup> A. vittata. Curt. Magaz. 129.—A. cripsa, figured by John Miller in his 8th Plate.—A. Atamasco. Curt. Magaz. 239.—A. lutea. Curt. Magaz. 290.—A. un-

Lily, which produces but one, or at most two, of its large, deep-red flowers, from the same sheath; the three under petals are larger than the others, and with the stamens and pistil are bent downwards; the whole flower stands nodding on one side of the stalk, and makes a most beautiful appearance, especially in the sun, when it appears

to be powdered with gold dust.

The Mexican Lily has several flowers, generally from two to sour, bursting from the same spathe; the corolla is bell-shaped and regular, the three outer petals are reversed or reslex at the tip, the three inner ones are ciliate at the base; the stamens and pissil are bent downwards. The slowers are large, of a bright copper colour, inclining to red; and the style is red, which is unusual: the base of the corolla is of a whitish green.

The Guernsey Lily has also many flowers in the same sheath, the corollas revolute, or rolled back, and the stamens and pistil upright. The corollas are of the richest red colour, powdered with gold. This fine flower is supposed to have come

R 4 originally

originally from Japan; and to have been left by a wrecked veffel on the coast of the island of Guernsey; where, being protected among the sand by the sea reed, it sprung up, to the great surprise of the inhabitants.

Tulipa.

The Tulip and some others which I shall now present to you agree with the Lily in having naked, unprotected corollas'. The Tulip w, unbounded in the variety of colour in the cultivated state of its gaudy flowers, has an inferior bell-shaped corolla of fix petals, and no style, but only a triangular stigma fitting close to a long prismatic germ. The species is distinguished by its short lanceshaped leaves, and its upright flowers, from the Italian Tulip\* whose flowers nod a little, have longer and narrower lance-shaped leaves, yellow corollas never varying in colour, ending in acute points, and having a fweet icent. The common colour of the Eastern Tulip, in a state of nature, is red. This, when broken into stripes by culture, has obtained the imaginary value of a hundred ducats for a fingle root, among the Dutch florists.

Convallaria. How different is the sweet, the elegantly-

<sup>\*</sup> Linnæus has fplit the liliaceous tribe, in his natural orders, into the Ensatæ before mentioned; the Spathaceæ, just gone through; and the Coronariæ, into which we now enter. Some also of this Sarmentaceæ belong to this tribe.

<sup>\*</sup> Tulipa Gesneriana Lin. Ger. 138. 3. 4. & 139—146. Thornton Illust. n. 1.

<sup>\*</sup> Tulipa fylvestris Lin. Fl. Dan. 375. Ger. 138. 1, 2. Engl. Bot. 63.

modest Lily of the valley, from the flaunting beauty of the Tulip! The pure bellshaped corolla is divided at top into six fegments, which are bent back a little: and the feed-vessel is not a capsule, as in most of this class, but a berry, divided however into three cells, in each of which is lodged one feed: this berry, before it ripens, is spotted. I doubt not but that you have often fearched for it in vain, because this plant seldom produces its fruit: the reason is, that it runs very much at the root, and increases so much that way as almost entirely to forget the other. I have feen large tracts covered with it, in the remote recesses of woods, without a single berry; and the way to obtain them is to imprison the plant within the narrow circuit of a pot, when, by preventing it from running at the root, it will take to increasing by the red berry. This species is distinguished from Solomon's-seal\*, and others. of the genus, by the flowers growing on a scape or naked stalk: it has only two leaves, which take their rife immediately from the root.

, The Hyacinth is one of the most favoured Hyacinplants of the florists. In the natural state, thus, wherein you seldom see it, the corolla is

y Convallaria majalis Lin. Curt. Lond. V. 24. Fl. Dan. 854. Ger. 410. This is one of the Sarmentacea in the natural orders.

<sup>\*</sup> Convallaria verticillata. Engl. Bot. t. 128 .- Mulziflora 279.—Polygonatam 280.

fingle, and cut into fix fegments; and there are three pores or glands, at the top of the germ, exuding honey. The species from whence all the fine varieties take their rise has the corollas funnel-shaped, divided half way into fix fegments, and swelling out at bottom. This must not be confounded with the Wild Hyacinth or Blue-bells of the European woods , which has longer, narrower flowers, not swelling at bottom, but rolled back at their tips: the bunch of flowers is also longer, and the top of it bends downwards. This is frequently found with white corollas.

Aloe.

Aloe is a remarkable, beautiful, and numerous genus, distinguished by its erect corolla, with a spreading mouth, divided into six segments, and exuding a nectareous juice at bottom: the silaments are inserted into the receptacle. Linnæus reduces them to ten species; but there are many very distinct varieties, if not species, under each. They have all thick succulent leaves, and the species may be separated either by the forms of these, or by the forms and manner of growth of the slowers.

Agave.

If you should hear of the Great American Aloe b flowering any where in your neigh-

<sup>&</sup>lt;sup>2</sup> Hyacinthus orientalis *Lin*. Mill. fig. pl. 148. Ger. 112—115.

<sup>&</sup>lt;sup>a</sup> Hyacinthus non scriptus Lin. Curtis, Lond. II. 18.

<sup>&</sup>lt;sup>b</sup> Agave Americana Lin. Figured in Dr. Thornton's Illustrations.

bourhood, you will find that it differs from the Aloes properly fo called, by the corolla being superior, or sitting on the top of the germ, and the filaments being longer than the corolla. In the first circumstance this differs from almost all the liliaceous tribe. which have the germ inclosed within the corolla. I should advertise you, that you must mount a ladder or scaffold to examine the flowers, for they grow on a stem that is fometimes twenty feet in height. You know it is a vulgar error that this plant flowers once only in a hundred years: the truth is, that in its own country it flowers in a few years from its birth; but in our cold inhospitable climes, it takes many years to produce its vast stem and numerous flowers. but the term of its life with us is uncertain: after having flowered, it produces a number of off-fets, and dies. This is not the case in the Aloes properly fo called, and in them the flowering stem is produced from the side of the heart or central leaves; whereas in this it issues from the very centre, where you observe that the leaves lie very close over each other before they expand.

Of plants not liliaceous, belonging to this first order of the fixth class, there is one shrub, the *Barberry*; and several plants desicient in the corolla, as the *Calamus Aro-*

maticus

<sup>&</sup>lt;sup>c</sup> Berberis vulgaris. Mill. fig. pl. 63. Ger. 1325. Engl. Bot. 49.

maticus or Sweet Rush d, the Rattane, and all the species of Ru/h f.

Oryza.

The Rice g is almost the only plant to be found in the second order of this class. It has the exact form and structure of the graffes, differing from them only in the number of stamens.

Rumex. In the third order is the Dock, a numerous and prolific genus, containing thirtyone species. It is known by the calvx of three leaves, the corolla of three converging petals, and one triangular feed. These plants will not attract vou by their beauty. Their flowers are more numerous than confiderable. Bloody Dock h has the valves of the flowers quite entire, one of them bearing a feed, and the leaves are lance-shaped and hollowed next the petiole. Curled Docki has the valves entire and graniferous; the leaves lance-shaped, waving about the edges, and sharp-pointed at the end. Fiddle-Dock k has the valves notched about the edges, one of them usually graniferous, and the leaves next the ground shaped like the

k Rumex pulcher Lin. Mor. Hist. s. 5. t. 27. f. 13.

body of a violin. The great Water Dock 1 has the valves entire and graniferous; the leaves lance-shaped and sharp-pointed: the common Blunt Dock has the valves notched and graniferous; the leaves oblong, hollowed at the base, near which they are notched, and obtuse at the end. Common Sharp Dock" has the valves oblong, entire, very small, the outer one graniferous; the leaves oblong and hollowed at the base, but drawn out into a long point. Two common species differ in one remarkable circumstance from all the rest; for they have the staminiferous and pistiliferous flowers on separate plants, and therefore strictly belong to the twenty-second class; but they are evidently, as you will confess upon examination, of the fame natural genus with the Docks. These are the Common\* and Speep SorrelP, the first growing in meadows and pastures, the second on dry fandy grounds; the first with oblong, arrow-head leaves; the fecond with leaves shaped like the head of a halbert. Thus you have the means of distinguishing eight species of Dock : as and the trans

Colchi-

Meadow-Saffron is also of this order, and clearly of the liliaceous tribe: its refemblance to Crocus or Saffron is obvious. Like that it has a fpathe for a calyx; a corolla divided into fix parts, with the tube extending down to the bulb; and a trilobate capsule, of three valves and three cells. So that, were it not that the one has three stamens with one style, and the other fix stamens with three styles, they would be of the same genus. Meadow-Saffron has stat, lance-shaped, erect leaves, and slowers of a light purple; the first coming out in the spring, the latter in the autumn.

Alifma.

Of the last order of this sixth class are the Water Plantains, easily known by the calyx of three leaves, the corolla of three petals, succeeded by several compressed capsules, each containing one seed. Great Water Plantain is common enough in wet places, and on the banks of rivers and brooks: it is distinguished from its sellows by its ovate sharp-pointed leaves, and its obtusely-triangular fruits. This is one of the plants in which you cannot err: if the differences of all were as strongly marked, your trouble would be diminished, but then your genius and sagacity, dear cousin, would not have so much room for exercise.

THE CLASSES HEPTANDRIA, OCTANDRIA, .... ENNEANDRIA, AND DECANDRIA.

June the 1st, 1775.

TATURE feems to have no delight in Æsculus the number feven; the feventh being the smallest of all the classes; containing no more than feven genera, and ten species. Of these I shall select only one for your obfervation, which shall be the Horse-chesnut's. It is of the first order, and these are the principal characters of the genus—a small calyx, of one leaf, flightly divided at top into five fegments, and swelling at the base; a corolla of five petals, inferted into the calyx, and unequally coloured; a capfule of three cells, in one or two of which only is a feed. Linnæus fays, that though no more than one feed generally comes to perfection, yet there are two in the young capfule. But furely the third cell is not made for nothing; and therefore I should suspect that in Asia, the native clime of this fine tree, the capfule contains three nuts. The form of the Horse-Chesnut is grand, the pyramids of flowers beautiful, and making, with the large digitate leaves, a fine whole.

<sup>\*</sup> Æsculus Hippocastanum Lin. Mill, Illustr. Hunt. Evel. Silva, p. 159.

## THE CLASS OCTANDRIA.

Tropæo lum.

The eighth class has forty-four genera, and two hundred and seventy-three species. Indian Nasturtium or Indian Cress' is one of these; the calvx is inferior, of one leaf cut into five segments, and terminated by a spur; the corolla has five unequal petals, and is fucceeded by three dry berries, in each of which is one feed. The greater species " is most common in the gardens, and is known by the leaves being divided at the edge into five lobes, and being peltate, or having the petiole fastened to the middle of the leaf's furface: the petals are blunt at the end in this: whereas in the smaller fort ' the petals are sharp-pointed. The corollas of both are large, and of a fine orange colour.

Oeno-

Tree Primrose, a Virginian plant now so common in the European gardens, has a calyx of one leaf, cut into four segments, a corolla of sour petals, and a cylindric capsule of sour cells, containing naked seeds. The broad-leaved fort w, which is most common, has slat, lance-shaped leaves, and a hairy stalk: the corolla is of a fine yellow, shut usually during the day, but expanding in the

<sup>\*</sup> Tropæolum Lin.

<sup>&</sup>quot; Tropæolum majus Lin. Curtis's Magaz. 23.

Oenothera biennis Lin. Fl. Dan. 446. Mill. Illustr. Most of the species are figured by Curtis.

evening; whence some call it Nightly Prim-

rose.

Our European Willow-herbs are nearly Epiloallied to this, differing only in having a bium. calyx of four leaves, and downy feeds. There is one fort common in old gardens called French Willow\*, with narrow lance-shaped leaves, inclining to linear, irregularly fet upon the stalk; irregular flowers, and stamens bent down. The hairy fort y growing common in wet places, by ditches, hedges, and streams, and vulgarly known by the names of Codlins and Cream, or Goofeberry Fool, from the smell of the leaves when slightly bruised, has lance-shaped leaves, serrate about the edges, running down the stalk, the lower ones opposite: the stamens of this and of all our common species are upright, and the petals bifid. Four of the filaments are short, and the other four rise to the top of the tube of the corolla, each four forming a regular square. I do not know whether it is generally so, but this year I could scarcely find any but what had been gnawn by infects: so that, if I had not known the plant well, I should have been puzzled to determine even the class. The flowers are large, specious, and of a purple colour.

The heath genus contains numerous spe- Erica. cies of lowly shrubs, which are by no means

<sup>\*</sup> Epilobium angustifolium Lin. Curtis, Lond. II. 24. Ger. 477. 7.

y Epilobium hirsutum Lin. Ramosum Huds. Curtis, Lond. II. 21. Ger. 476. 6.

destitute of beauty, though the commonness of one species renders it contemptible 2. They all agree in these characters—a calyx of four leaves inclofing the germ, a corolla of one petal, cut into four fegments; the filaments inferted into the receptacle; the anthers bifid; and a capfule of four cells.

Common Heatha, which is so general a plant, that vast tracts of land take their name from it, is distinguished by the anthers being terminated with an awn, and lying within the flower, the style appearing behind it, the corollas bell-shaped, and not quite regular, the calvxes double, the leaves oppofite and shaped like the head of an arrow. Fine-leaved Heath b, has crested anthers lying within the corolla; the style hardly iffues from it; the stigma is capitate; the flowers grow many close together; the corollas are ovate and of a blueish colour; the leaves are produced in threes; and the bark is ash-coloured. Cross-leaved Heath has the anthers as in the first; the style lies within the corolla; the flowers grow in a head; the corollas are ovate; and the leaves are produced in fours: this grows in the wet and boggy parts of heaths, and is a

<sup>2 &</sup>quot; E'en the wild heath displays its purple dies."

<sup>&</sup>lt;sup>a</sup> Erica vulgaris Lin. Curtis, Lond. V. 30. Fl. Dan. 677. Ger. 1380. 1.

<sup>b</sup> Erica cinerea Lin Curtis, Lond. II. 25. Ger.

handsome species. The foreign forts, mostly from the Cape of Good Hope, are eminently beautiful. Some of them are finely figured in a splendid work by Bauer. It is said that the Cape alone surnishes more than 250 species of heath.

Mezereon, which you value for vifiting Daphne.

you at a time when you have very few visitors, and also for its pleasant odour, is of this class, and of the first order, as well as all the foregoing. It has no calyx, but a monopetalous, funnel-shaped corolla, inclosing the stamens, and the border cut into four segments: the fruit is a roundish berry containing one seed. This species is distinguished from the rest of the Daphne genus by its sessile flowers, growing by threes from the same joint; and by its lance-shaped deciduous leaves. The corollas are peach-coloured, deeper red, or white; and the berries of the two first are red, of the last vellow.

There is a forte not uncommonly wild in woods, and shady hedges, which is an evergreen, and has the flowers coming out by fives, from the axils; the corollas are of a yellowish green, and the leaves are lanceshaped. This is rather a dismal plant in respect of its situation, time of flowering,

d Daphne Mezereum Lin. Fl. Dan. t. 268. Ger.

Daphne Laureola Lin. Spurge Laurel. Ger. 1404. Blackw. 62. Engl. Bot. t. 119.

and colour of the corollas; nor has it the fame agreeable fcent with the Mezereon; it is not however without its value as an evergreen, and flourishing under the deep shade of trees. Both species are very hot and caustic in their nature; notwithstanding which, birds are greedy of the berries.

Chlora.

Yellow Perfoliate Gentians is now removed from the other Gentians to the second order of this class, because the number eight prevails in the stamens, calyx, and corolla: the style is really simple, but the stigma is four-cleft: in other circumstances it agrees with the genus in which it formerly ranged. It is found in pastures, on a chalky soil, and is easily known by its yellow corollas, and upright smooth perfoliate stalks.

Polygonum. The third order has a large genus containing twenty-seven species, among which, besides other common plants, are Bissort, Knot-grass, Buck-wheat, and Black Bindweed.

Bistort has a single, undivided stalk, terminated by one spike of slowers; and lance-shaped leaves, generally hollowed at the base, running along the petiole, or forming a membrane along each side of it, and waved. The root is large for the size

f Chlora perfoliata Lin. Ger. 547. 2. Engl. Bot.

B Polygonum Bistorta Lin. Curtis, Lond. I. 22. and Mill. sig. pl. 66. Ger. 399. 1. Engl. Bot. 509.

of the plant, and turns and twists in the

ground.

Knot-grass is a very common weed in places that are trod. The little flowers are produced from the axils of the stalks, which are herbaceous, and trail upon the ground; the leaves are lance-shaped, and, being of different size and breadth in different soils, have given occasion to the forming distinctions which are but varieties.

Buck-wheat i, which makes a pretty appearance when cultivated, has arrow-shaped leaves hollowed at the base, the stalk upright, though weak, smooth, and unarmed,

and the angles of the feeds equal.

Black Bindweed<sup>k</sup> is not very unlike this; but the leaves are heart-shaped, the stalk angular and twining, and the flowers obtute. The anthers also are purple; and the base of the petioles is perforated beneath with a pore. This is not an unfrequent weed among corn.

All the species agree in having no calyx; a corolla divided into five segments, that might easily be taken for a calyx; and one

naked, angular feed.

b Polygonum aviculare Lin. Curtis, I. 27. Ges. 565. Fl. Kust. t. 91.

Polygonum Fagopyrum Lin. Ger. 89. Fl. Rust. t. 46.

k Polygonum Convolvulus Lin. Curtis, Lond. IV. 29.

### THE CLASS ENNEANDRIA.

The ninth class has not fo many genera as the feventh, but it has many more species 1, and among them feveral very remarkable ones; as the Bay, Cinnamon, Cassia, Camphor, Benzoin, and Sassafras, all comprehended under one genus"; Acajou or Laurus. Cashew Nut, and Rhubarb. The Bay genus has the following character: no calyx, but a corolla refembling a calyx, and divided into fix parts in most of the species; a nectary of three glands, each terminated by two briftles, furrounding the germ; the filaments in three rows, with two round glands near the bale of the three that form the inner row; the fruit an oval drupe or plum, inclosing a nut.

The true Bay n is known by its lancefhaped veiny evergreen leaves; the corolla recedes from the general character in being quadrifid or cut into four fegments. It varies also in the number of stamens from eight to fourteen; and it recedes from the class in having incomplete flowers on separate plants. Linnæus however has kept it here

because

<sup>1</sup> Twenty-eight: and only fix genera.

m Laurus.

n Laurus nobilis. Laurel is known only to modern times, and ranges in the class leofandria under Prunus. Alexandrian Laurel is a Rufcus in Class XXII.

because it has the effential characters of this genus, particularly the glands on the inner filaments. You will scarcely have the good fortune to meet with the other species, at least in flower. 4 moust be

Acajou or Cashew we know chiefly by Anacarthe nut, which grows at the end of a fleshy dium. body as large as an orange, and full of an acid juice; this Linnæus calls the receptacle. Between the two shells is a thick, black, inflammable oil, with which you may mark your linen, for it will not wash out. It also makes the finest black varnish. I need not caution you against putting this nut into your mouth to crack it. The oil is very caustic, and will raise blisters in the tongue. If it should ever be your fortune to see this tree in flower, you will observe that the calvx is five-leaved; that the corolla confifts of five reflex petals; and that there are ten filaments, whence Linnæus first put it into the tenth class; but one of these being constantly without an anther, he afterwards removed it to the ninth. More recent observations however have ascertained that the Anacardium has perfect and staminiferous flowers on distinct individuals: it belongs therefore to the fecond order of the twentythird class, Polygamia Dixcia.

These are of the first order, Rhubarb is Rheum. of the second, Triginia; there being no plants known of this class with two pistils.

<sup>•</sup> Anacardium occidentale Lin.

The characters of this genus are—a flower without a calyx; a corolla of one petal, divided into fix fegments; and one large triangular feed, much like that of the Docks P. No less than four species have been fent over and cultivated at different times under a notion of their being the true Tartarian Rhubarb. Of thele the Rhapontick has migrated from the apothecary's shop into the kitchen, the petioles of the leaves being much esteemed for making tarts. The leaves are smooth, of a roundish heart-shape, with the petioles thick, reddith. a little channelled on their lower part, but flat at the top: the flower stems are red. grow from two to three feet high, and are terminated by thick, close, obtuse spikes of white flowers, coming out in June. This grows wild near the Pontic, Euxine or Black Sea.

There is a good testimony for the three others being the true Rhubarb; and I think it not improbable but that they may all be cultivated in Tartary for their roots. One of these has longer leaves than the Rhapontick, running more to a point, much waved on their edges, a little hairy on their upper side, and they appear much earlier; the petioles are not so much channelled on their

P They are both placed in the fame natural order, namely the fifth division of the Oleracea.

Rheum Rhaponticum Lin.
Rheum Rhabarbarum Lin.

under side, and are plain on the upper; they are also neither so red nor so thick: the flower stem is of a pale brownish colour, about sour feet high, dividing into several loose panicles of white slowers, which ap-

pear in May.

Another has very fmooth, shining, heart-shaped leaves, not running out so much to a point as the second, but more than the first; they are very broad towards the base, and a little waved and indented on their edges: the petioles have scarcely any channels, and are flat on their upper side; they are pale green, and almost as large as those of the first sort. The slower-stem is pale green, five or six seet high, the upper part dividing into small branches, each sustaining a panicle of white slowers standing erect, and appearing the latter end of May.

A fourth fort, called Palmated Rhubarb; differs greatly from the others, and is known immediately by its palmated and very sharp-pointed leaves. The flower stem is red, and six or seven feet high: the flowers are in loose panicles. Whatsoever may be the case with the other species, there is the most undoubted evidence of this being the true

Tartarian Rhubarb.

There is one wild plant of this class, Butomus

Rheum compactum Lin. Mill. fig. pl. 218.

Rheum palmatum Lin. Mill. Illustr. Philos. Trans. 1765.

which is of the third order, having fix styles. It grows in the water, and having handsome rose-coloured flowers, with long narrow leaves, is called Flowering Rush's; the slowers are produced at the end of a naked stalk, in an umbel. They have no calyx, but a three-leaved involucre, a corolla of fix petals, and fix captules of one valve, gaping on the side towards the centre of the umbel, and containing many seeds.

### THE CLASS DECANDRIA.

The tenth is a much more confiderable class, having ninety-five genera, and five hundred and thirty-fix species. The first order being very numerous, Linnæus has made a commodious subdivision of it into fuch as have corollas of many petals, of one petal, or none; and the first of them he has fubdivided again into fuch as have irregular and fuch as have equal corollas. Most of those with irregular polypetalous flowers are very nearly allied to the papilionaceous tribe, with which you are already acquainted. Of these the most known are the Judas-tree, Locust-tree, Flower-fence, Brafiletto, all the numerous species of Cajjia, Balfam of Tolu-tree, and Nickar-tree; mostly the produce of South America and the West

Indies.

<sup>&</sup>quot; Butomus umbellatus Lin. Curtis, Lond. I. 29. Fl. Dan. 604. Mill. Illustr. Mor. s. 12. t. 5. s. penult. Ger. 29. Engl. Bot. 651.

Indies. White Dittany or Fraxinella is also of this subdivision, but not of the papilionaceous tribe.

This elegant flower is known by its five-Dictamleaved calyx; its corolla of five spreading nuspetals; the filaments set with glandulous points: it is succeeded by five connected capsules, containing two seeds covered with a common aril.

There is only one species of Fraxinella, varying in the colour of the flowers, which are either pale red striped with purple, or else white. It has pinnate leaves, somewhat resembling those of the Ash. The whole plant emits an odour of lemon peel, but when bruised has a balsamic scent.

Among the plants with regular or equal polypetalous corollas, you will find Logwood, Melia or the Bead-tree; Guaiacum, Rue, and Dionæa Muscipula, so curious for that sensitive quality of the leaves, by which it

entraps intects that light upon them.

Rue is distinguished by these generic Ruta. characters—a calyx divided into five parts; concave petals; ten heneyed pores at the base of the germ, which is raised on a receptacle punched with the same number of pores; and lastiy, a capsule cut half way into five parts, consisting of five cells within, and containing many seeds. It I do not give you a caution respecting the common

y Dictaumus albus Lin. Mill. fig. pl. 123. & Pl. 16. f. 2. of this work.

Rue w of the gardens, you may probably be puzzled in examining its flowers; for there is only one flower on a branch which will answer to the generic characters; in all the rest you are to subtract one fifth from every part of the fructification. This circumstance is not peculiar to Rue, but is found in feveral other plants\*, and has been made an objection by some to the Linnæan system. The illustrious author has extricated himself from the difficulty by forming his character upon the principal or primary flower, as he calls it, and announing the anomaly. There are other plants, which, in all the rest, add a fifth to the number of parts in the primary flower y.

Garden Rue is specially distinguished, partly, by this circumstance, of having the side slowers quadrisid, and partly by the leaves being decompounded. There are some differences in this species: common Garden Rue has the component lobes of the leaves wedge-shaped, and the stamens longer than the corolia; another, also frequently cultivated, has narrower lobes, the slowers in longer, looser bunches, and the stamens equal in length with the petals; the seed-

Thesium alpinum, Herniaria fruticosa, Gentianæ 23—
27. Linum Radiola, &c.

veffel is also smaller; a third has the lobes

of a linear shape.

Andromedas, Rho. lodendrons, Kalmias, Arbutus, and a few others, have regular monopetalous corollas. The characters of the last are—a very small calyx divided into five parts: an ovate corolla pellucid at the bate: and the fruit a berry, with the feeds lodged in five cells.

Strawberry-tree 2 is known by its woody Arbutus. stem, its smooth leaves serrate about the edges, and the cells of the berries having feveral feeds. Some of the other species have weak procumbent stems a; and some have only a simple feed to each cell b. You are well acquainted with the Arbutus, by the ornament which it affords to your plantations in the latter months, with its lucid leaves thick covering the plant; and its bunches of flowers of this year, accompanied by the red round berries of the last.

But let not the first order of the tenth Saxifraga class occupy too much of your time, fince there are four other orders contained in it. In the fecond you have all the Saxifrages, forty-two in number; agreeing in a calyx divided into five parts; a corolla of five petals; a capfule of one cell, filled with many small feeds, and terminated by two beaks

<sup>&</sup>lt;sup>2</sup> Arbutus Unedo Lin. Mill. fig. pl. 48. Get. 1496.

<sup>&</sup>lt;sup>a</sup> Arb. acadienfis, alpina & uva urfi.

formed of the permanent styles. Of these, Pyramidal Saxifrage is esteemed for adorning halls and chimneys with its beautiful pyramids of white slowers; which it will do for a long time. There are several varieties of it, but they have all stiff tongue-shaped leaves, with a cartilaginous serrate border, and collected into several rows close to the ground. From the midst of these issues the stalk, sustaining the panicles of slowers.

Another species was formerly much shown out at windows and balconies in smoky towns, and hence with its being really beautiful, had the names of London Pride and None-so-pretty, at a time when sew plants were generally known. This has oblong or roundish leaves, deeply notched on the edges, springing from broad, flat, surrowed petioles, near two inches long. They surround the flowering stalk, which itself is destitute of leaves, of a red colour, stiff, slender, and hairy. The corollas are white dotted with red.

Common White Saxifrage flowers early and in great quantities among the grafs. The bottom leaves are kidney-shaped, hairy, and on pretty long petioles: the

<sup>&</sup>lt;sup>c</sup> Saxifraga Cotyledon *Lin*. Mill. fig. 243. Fl. Dan.

d Saxifraga umbrofa *Lin*. Mill. fig. 141. f. 2. Engl. Bot. 663.

Saxifraga granulata Lin. Mill. Illustr. Curtis, Lond. I. 30. Ger. 841. 1. Figured also by Dr. Thornton in n.6. of his splendid work.

stalks are hairy, and in good ground a foot high, branching out from the bottom, and furnished with a few small leaves, in shape like the others, but sitting close to the stem: the slowers terminate the stalk in small clusters; the corollas are white, and large for the size of the plant: if any doubt remains concerning it, pull it up, and you will find that the roots are like grains of corn, and of a reddish colour. In poor ground this plant is very small, and has only two or three slowers, sometimes but one, on a simple unbranched stem.

These, with most of the other species, have upright stems; but there are three which have weak trailing stalks. Of these there is one which has much resemblance to a moss, when it is out of flower; and, from the manner of its growth in a thick tust, it has acquired the English name of Ladies' Cushion. The leaves are linear, some entire, and others trisid: the little flower stems are three or four inches high, slender, erect, and almost naked, terminated by small flowers of a dirty white.

The genus Dianthus, of this fecond or-Dianthus. der, is numerous, as well as the last, comprising twenty-two species, which agree in having a cylindric calvx of one leaf, surrounded at the buse by four scales; a corolla of sive petals; and a cylindric, unilo-

f Saxifraga hypnoides Lin. Fl. Dan. 348. Mor. Hist. f. 12. t.9. f. 26.

cular capfule, for a feed-veffel. Many of the species are beautiful, as Sweet William's the noble Carnation h, the Pink i, with all its numerous varieties, the China Pinkk distinct from the former: several also of the forts which are wild in many parts of Europe, though adorned with less splendid flowers, and more modest in their pretenfions, are not however without their beauty. The Carnation is acknowledged, on all hands, for a worthy leader of one of the finest natural orders, entitled, from the Latin name of this fragrant flower, Caryophylleous plants. When we consider the fize of the flower, the beauty of its colours, the arrangement of its parts, and above all the fingularly rich and spicy odour that it exhales, we cannot withhold that tribute of admiration which will ever be given it, unless, by obtruding itself too frequently on the eye, its real beauties become at length difregarded.

The leading feature, in distinguishing the species of this genus, is the inflorescence, or manner of flowering. Sweet William and some others have aggregate flowers; Carnation, Pink, China Pink, &c. have

Burbatus Lin. Engl. Bot. 205.

b Dianthus Caryophyllus Lin. Mill. fig. 121. Engl. Bot. 214. Curt. Magaz. 39.

Dianthus plumarius Lin.

Lin. Mill. fig. pl. 81. f. 2. Curtis's Mag. 25.

many flowers on the same stalk, not however in herds, but folitary or feparate; some few have one flower only on a stem: and two or three have shrubby stalks. The other circumstances that discriminate the fpecies are, that the scales at the base of the calyx in the Sweet William are of an ovatefubulate form, and as long as the tube of the corolla; in the Carnation and Pink they are subovate and very short; in the China Pink they are subulate, as long as the tube, and hang loofe. The Sweet William has also lance-shaped leaves. Carnation and China Pink have the petals notched. The Pink has the corollas pubefcent at the base. and the petals deeply cut. For ornament and beauty you will gather these flowers from your parterre; but as a Botanist you will take them from a wall, or a dry untilled foil, where their fimplicity and the clearness of their natural characters will make you full amends for the want of fplendour. You would not always choose to be among full-dreffed people at a ball, or in a drawing-room; but fometimes to take a rural walk, and entertain yourself with plain country manners.

In the third order, besides some others, Arenathere are sour genera containing many spe-ria, &c. cies which have a good deal of similitude. They are however thus well distinguished. Arenaria and Stellaria have a capsule of one cell; Cucubalus and Silene, a capsule of three

T

cells: of the two former the first has the petals entire, the second has them bisid: of the two latter, in both of which the petals are bisid, the second has a crown composed of a set of minute petals in the centre; whereas the first has nothing of this, or is naked. Arenaria and Stellaria have also a five-leaved calyx; in Cucubalus it is much instance, and in Silene it is swelling. All four have five petals in the corolla.

Cucuba
Spatling Poppy<sup>1</sup> is not an uncommon weed among corn and in meadows. You will know it by the almost round and much inflated calyx, beautifully veined, so as to have the appearance of a fine network thrown over it, and quite smooth: the corollar are not entirely naked, and are pure

Cadum

white.

Sedums or Stone-crops are found in the fourth order (Pentagynia). They are known by the general prevalence of the number five in all parts of the flower: a calyx cut into five fegments, a corolla of five petals, five nectariferous scales at the base of the germ, and five captules: not to mention the twice five stamens, and five styles, which form the characters of the class and order. Many of them are not uncommon in a wild state, particularly a small trailing fort with yellow slowers growing in a trifid

<sup>&</sup>lt;sup>1</sup> Cucubalus Behen Lin. Fl. Dan. 857. Mor. Hift. f. 5. t. 20. f. 1. Ger. 678. 2. Blackw. 268. Engl. Bot. t. 164.

cyme; and ovate, blunt, fmooth leaves, imbricate and alternately adhering to the stalk ": other species have white, and some red corollas. They grow chiefly on walls,

or in very dry foils.

Cocklen, which is so common a weed Agroamong corn, has a membranaceous, one- flemma. leafed calyx; a corolla of five obtufe, undivided petals, and an oblong capfule of one cell. The species is distinguished by the roughness of the plant, the length of the fegments of the calyx, and by the petals being entire and naked.

Of Lychnis there are several species agree-Lychnis. ing in these common characters: An oblong fmooth calyx of one leaf; a corolla of five petals flightly bifid; and a one-celled

capfule of five valves.

Scarlet Lychnis', commonly cultivated in gardens, has the flowers growing in bunches, fo that the whole forms nearly a flat furface at top; the colour of the corolla is a very high scarlet. There was a

Catchfly<sup>p</sup>, fo called from the clammy juice exuding from the stalks under each pair of leaves, glutinous enough to entangle

Lychnis Viscaria Lin.

fmall flies, is known by the petals being almost entire; the colour of them is red: the leaves are long, narrow, and grass-like, especially the lower ones. The flowers of this and the foregoing are usually double in the gardens, and therefore useless to you in

your botanical refearches.

There is a fort of Lychnis commonly wild by water-fides and in moist meadows, called Ragged-Robin, Meadow-Pinks, Wild-Williams, or Cuckow-flower, which has red jagged petals, generally cut into four parts; and roundish capsules, the mouth of which has five teeth turning back. There is also another no less common in pastures, called White Lychnis, or White Campion, which differs essentially from its congeners in having the pistils separate from the stamens, and on distinct plants. I leave you, dear cousin, with this irregularity, and wait a day of leisure to pursue our botanical career.

# LETTER XX.

#### THE CLASS DODECANDRIA.

June the 10th, 1775.

OTHING difficult has hitherto occured, dear coufin, in your determination of the classes, the number of the stamens alone having sufficed for that purpose. But no plant being yet discovered with eleven stamens, among those which have them distinct's, the eleventh class should be expected to contain those plants which have twelve; but here the number is found to be by no means constant, and Linnæus is obliged to take in to his class Dodecandria, all fuch plants as have from twelve to nineteen stamens inclusive. Nor is the eleventh class. with all this latitude, an easy one for a novice to determine; the number of stamens in some cases being fewer than twelve, in others more than nineteen, or else coming out in parcels at different periods. It is not very numerous, containing but thirty-three genera and one hundred and fixty-four species.

Of the first order, the most known or the most remarkable are Afarum or Asarabacca,

3

s Brownea, which has naturally eleven stamens, is of the fixteenth class, Monadelphia.

the Mangosteen, Winter's Bark, Purslain,

Loosestrife.

Asarum. Asarabacca has a calyx cut half way into three segments, and sitting on the top of the style: no corolla: and a leathery capsule, of six cells within, and crowned at top. There are three species—the Canadian, the Virginian, and the European, which last is distinguished by two kidney-shaped leaves, ending bluntly.

Portulaca Purstain has a bifid calyx inclosing the germ; a corolla of five petals; and a capfule of one cell, in which the receptacle is loose; in some species it opens horizontally, in others it is trivalvular: the number of stamens varies in the different species. The Purstain, cultivated for sallads, is a native of the hot parts of America: it is known by its wedge-shaped leaves, and the flowers sitting close to the stalk: and it is one of those which have the capsule opening horizontally.

Lythrum. Loosestrife has the calyx cut at the edge into twelve portions, and inclosing the germ: the corolla of fix petals, inserted into the calyx: the capsule bilocular, and containing many seeds. Purple Loosestrife is a handsome plant, adorning the banks of

Afarum europæum Lin. Fl. Dan. 633. Mill. fig-

u Capsula circumscissa.

v Portulaca oleracea Lin. Blackw. t. 287. v Lythrum Salicaria Lin. Curtis, Lond. III. 28. Ger. 476. 5.

rivers, ponds, and ditches, with its fine spikes of purple flowers; the leaves grow in pairs and are lance-shaped, with a hollowed base: fometimes three leaves come out together from the same point, and the stalk is hexangular: but this is only an accidental variety. Our species answers to the character of the class in having twelve stamens; but there are some which have but ten,

nay even only fix stamens.

In the fecond order are only two genera Agrimo--Heliocarpus, an American plant, little nia. known; and Agrimony, an European, and fufficiently common. This has a small quinquefid calyx, fitting on the top of the germ, fortified with another: a corolla of five petals, inferted into the calyx, and one or two roundish seeds in the bottom of the calyx. The number of stamens is very uncertain in this genus; fome species having twelve, others ten, others feven. Common Agrimony\*, which is found in woods and by hedge-fides, has interruptedly-pinnate leaves on the stalk, with the leastet at the end petiolate; the feeds are fortified with briftles. The outer calyx grows fast to the inner; and the stamens vary in number from twelve to twenty.

The third order has also only two genera, but they are numerous; Reseda having twelve and Euphorbia no less than fixty-nine species.

<sup>\*</sup> Agrimonia Eupatoria Lin. Curt. Lond. V. 32 Fl. Dan. 588. Mill. Illustr. Ger. 712. Fl. Rust. t. 37.

No genera are more difficult to determine than these; the number and form of the parts varying in the different species. The effential character of the first consists in the trisid petals, one of them malliserous at the base; and in a capsule of one cell always open: the calyx also is of one leaf, cut into several narrow segments, two of which gape more than the others on account of the melliserous petal; the stamens are from eleven to sisteen in number.

Reseda.

Dyer's-weed or Weld' grows common in barren paftures, dry banks, and on walls; it is also cultivated for the use of the dyers. The leaves are lance-shaped, and entire, except that they have one indentation on each side at the base; and the calyx is cut into four segments. The corolla also has three petals: the upper one melliterous, and divided half way into six parts; the opposite lateral petals are trisid; and sometimes two small entire petals are added below. Dyer's weed is a biennial plant, producing the first year a circle of leaves close to the ground; and the next a stalk terminated by a long loose spike of yellowish slowers.

Sweet Reseda, or Mignionette2, has oblong

Reseda Luteola Lin Fl. Dan. 864. Ger. 494. Fl. Rust. t. 40. Engl. Bot. 320.

<sup>&</sup>quot;This is thought to be the plant with which the ancient Britons dyed their bodies.

<sup>&</sup>lt;sup>a</sup> Reteda odorata *Lin*. Mill. fig. 217. Curt. Magaz. 20.

leaves, some of which are entire, and others trifid; the calyx of the flower is large, equalling the corolla in fize. The flowers are produced in loofe spikes, on long peduncles; are of an herbaceous colour, and much esteemed for their agreeable odour,

like that of fresh Raspberries.

Euphorbia has a corolla of four, and Euphorfometimes of five petals, glandulous in most bia, species, in some shaped like a crescent, or indented about the edges, in a few thin as a fine membrane; commonly placed as it were on the outfide of the calyx, which is of one leaf, divided at the edge into four, or in some into five parts, and ventricose or fwelling out. The stamens are twelve or more, iffuing forth at different periods. The feed-vessel is a capsule of three distinct cells united, with one roundish feed in each cell, and on the outfide fmooth, rough or warted in the different species. This genus being to numerous, some subordinate distinctions are necessary; and accordingly Linnæus has divided it into seven sections. The first contains the Euphorbia properly so called; or such as have a shrubby, angular, spiny stem, generally void of leaves. The fecond contains the shrubby species, without spines. In all the other tections the stems are dichotomos, or divide always by pairs, and the flowers are borne in a kind of umbel, which, in the third fection, is commonly bifid; in the fourth, trifid; in the

the fifth, quadrifid; in the fixth, quinquefid;

and in the seventh, multifid.

Several species of the first section yield indifferently that acrid milky juice, which, when inspissated, is sent us under the title of Euphorbium. The flowers are of little beauty, and these plants have been noticed rather for the fingularity of their form, and the firiking difference of their structure, from the plants of Europe, than for any charms that they possess. The species supposed to be that from whence the ancients had the drugb, is known by a triangular, jointed stalk: the species from which it is said we now have it c, has a quadrangular stem, and double spines: and the species which Linnæus supposes ought to be used d, is multangular with double spines.

Medusa's-heade is of the second section. The stalks are closely covered with tubercles, lying over each other, and from the sides of these spring many branches, which are frequently so entwined as to give the idea of a parcel of serpents. The ends of the branches have narrow succulent leaves readily dropping off, and a set of white

flowers.

The plants of the other sections are com-

b Euphorbia antiquorum Lin. Comm. hort. 1. t. 12.

<sup>&</sup>lt;sup>e</sup> Euphorbia canarienfis *Lin*. Comm. hort. 2. t. 104. <sup>d</sup> Euphorbia officinarum *Lin*. Comm. hort. 1. t. 11.

<sup>&</sup>lt;sup>e</sup> Euphorbia Caput Medufæ Lin. Comm. hort. 1.

monly known by the name of Spurge, and are most of them wild in the different parts of Europe. Two species are common weeds in kitchen gardens; one of them\* belongs to the fourth fection, or those which have trifid umbels: the fubdivisions of these are dichotomous: the involucella or bractes are ovate; and the leaves are quite entire. or without any notches about the edge: they are ovate in form, and attached to the stalk by short petioles; each petal also has two little horns: the other s is of the fixth fection, having quinquefid umbels; each principal division subdivides into three; the involucellæ are shaped as in the former; the leaves are wedged-shaped, and serrate about the edges; and the petals are round and entire. A third species h, common in woods. is of the last section with multifid umbels: it is a larger plant, and perennial; whereas the others are annual: the involucella are round and perfoliate; the leaves are very blunt at the end.

Spurges having little beauty, they are feldom cultivated in gardens We must however except the Euphorbia punicea, a most splendid Jamaica plant, which slowers in

Euphorbia Peplus. Petty Spurge. Curtis, Lond. I.

<sup>35.</sup> Ger. 503. 19.

Euphorbia helioscopia Lin. Sun Spurge. Curtis, Lond. I. 36. Ger. 498. 2.

the collection of the Marchioness of Rockingham, and is admirably figured in Dr. Smith's Icones Picta. This belongs to the fifth fection. One of the most common is a biennial species, of the same section, with the leaves opposite and quite entire, called Broad-leaved Spurge or Cataputiai. Its native place is Italy, and the fouth of France: it grows three or four feet high; the flowers are of a greenish yellow, and the capfules being very elastic, the seeds are thrown to a confiderable distance. A second is perennial, and of the last section k; the involucellæ are heart-shaped; the petals are formed like a crefcent; and the captules are fmooth; some of the branches are barren, and others bear flowers and feed; on the first the leaves are narrow and setaceous; on the fecond they are lance shaped.

vivum.

Semper- There is a genus of this class in which the number twelve prevails in all the parts. Having twelve styles, it is of the order Dodecagynia. The calyx is divided into twelve parts; the corolla confifts of twelve petals; and the flower is succeeded by twelve capfules, containing many fmall feeds. Common Houseleek m is one of these, which, though

Euphorbia Lathyris Lin. Mill. Illust.

Euphorbia Cyparissias Lin. Blackw. 163. f. 3. 1 Sempervivum; nearly allied to the Sedums in the tenth class.

fo succulent a plant, flourishes on walls and roofs. The edges of the leaves are fet with short fine hairs; and they do not grow in a globular form, as some other species do, but spread open. From the centre of the heads of leaves arises a round, red, succulent flower-stalk, about a foot high, which at bottom has a few narrow leaves, and at top divides into two or three parts, each supporting a reflex range of flowers, with red corollas. Though the natural number in this genus be twelve, yet you will find it to vary exceedingly: nature being less constant in larger than in smaller numbers. With this short sketch, adieu, dear cousin, for the present.

## LETTER XXI.

THE CLASSES ICOSANDRIA AND POLYANDRIA.

June the 21st, 1775.

an imperfect view of the twelfth class, as far as it relates to fruit-trees. you are not however to suppose, either that all these trees range in the class Icosandria, or that no other but them are to be found there. No less than twenty-nine genera, and two hundred and ninety-four species, are included in this class, a considerable portion of which is trees or shrubs; many herbs however are found among them.

To distinguish this class and the next from the rest, and from each other, remember always that it is not the number, but the situation of the stamens which surnishes the classical character. In the next they arise, as generally in the other classes, from the receptacle; but in this they spring either directly, or with the parts of the corolla, from the calyx o, which is of one leaf, and not slat but hollow: the corolla is most fre-

quently of five petals.

Of the first order, Caetus is a very con-Caetus. fiderable genus, comprising the Melon-thistles, Torch thistles, or Cereuses, and the Opuntias or Indian Figs. These all agree in a calyx, whole at the bottom, but yet consisting of several rows of leaves, and placed on the top of the germ: in a corolla which is double, or formed of several rows of petals: and in having a berry containing several seeds in one cell.

The Melon-thisseless are roundish bodies, without either leaf or stalk. The Torch-thistes have a long stem without leaves, which in many species is strong enough to support itself; but in some trails along the ground, or is supported by trees: these last are called Creeping Cereuses. Opuntias are composed of stat joints connected to-

gether.

These are all remarkable for a structure different from that of other plants; but some of the Cereases are much esteemed for the beauty of the flowers, which are perhaps the more noticed, because they are the less expected from plants whose appearance is so unpromising. Those of the Great Flowering Creeping Cereus p are near a soot in diameter, the inside of the calyx of a splendid yellow, and the numerous petals of a pure white: hardly any flower makes so magnificent an appearance during the short

P Cactus grandistorus Lin. Mill. fig. pl. 90. Thornton, n. 6.

time of its duration, which is one night only; for it does not begin to open till seven or eight o'clock in the evening, and closes before sun-rise in the morning, unless it is gathered and kept in the shade, by which means I have prevented it from closing till about ten. This noble slower opens but once; but when, to the grandeur of its appearance, we add the fine perfume which it disfuses, there is no plant that more deferves your admiration. When it is not in blow, you will know it by the creeping stem, marked longitudinally with about five prominences.

Another species of Creeping Cereus is more common, but scarcely lets admirable for the beauty of its pink-coloured flowers, which the plant produces in greater quantity; they are also of longer duration, for they not only boldly show their face to the sun, but will even keep open three or four days. When it is not in flower, this species is distinguished by its very slender branches, covered with spines, and marked with ten prominences. But you are well acquainted with this sine plant, which, requiring lattle heat, forms one of the principal ornaments of your dressing-room, in the month of May.

There are many species of Opuntia, Indian Fig, or Prickly Pear, all natives of

America,

<sup>9</sup> Cactus flagilliformis Lin. Ehret. pict. t. 2. Trew. Ehr. t. 30. Curtis's Mag. 17.

America, and kept rather for their fingularity than their beauty, having no leaves, but a flat jointed stalk, set with knots of prickles, bristles, or both. The Cochineal Fig', on which the insect of that name feeds, is the only one that is unarmed: this has oblong joints: the common fort has roundish joints, with brushes of bristles, but no prickles.

In this same order you will find the Sy-Philadel-

ringat. The natural number in the calyx, phuse corolla, and capfule, is four; but fometimes it is five. The taste of the leaves, like cucumbers, and the odour of its white flowers, like those of the orange, sufficiently distinguish this well-known shrub from all others. The slight indentations about the edges of the leaf separate it from another species, which has none.

Here too will you find your favourite Myrtus, Myrtle, which has a calyx fitting on the top of the germ, and generally cut into five fegments; a corolla of five petals; and a berry for a fruit. Some species however have a quadrifid calyx, and then the corolla has four petals: others have an entire undivided calyx. The Common Myrtle<sup>u</sup>, of which there are many varieties, has the

Philadelphus coronarius Lin. Duham. arb. 83. Curt. Magaz. 301.

Myrtus communis Lin. Mill. fig. 184.—Pl. 18.

flowers coming out fingly, and an involucre of two leaves upon the peduncle.

Cratæ-

In the fecond order there is only the Cratægus, a genus comprehending several species of Thorn, and also two trees, the Aria or White Beam Tree', and the Mapleleaved Service". The generic characters are—a calyx cut into five fegments, and fitting on the top of the germ; a corolla of five petals; and a berry containing two feeds. The first of the trees is readily known by the ovate shape of the leaves, with very prominent transverse veins, and unequal ferratures about the edges; but particularly by the hoariness of their under furfaces: the fecond, by its leaves cut into many acute angles like those of the Maple: the divisions are five or seven; and the lowest lobes stand wider than the others. Cockfour Hawthorn has the leaves ovate, and so deeply serrate as to be almost lobed. Virginian Azaroley has oval leaves wedgeshaped at the base, shining, and deeply serrate. Common Hawthorn, or White-thorn. whose flower has obtained the name of

<sup>&</sup>lt;sup>2</sup> Cr. Oxyacantha Jacqu, austr. 292. 1. Blackw, 149. 1. Ger. 1327. 1.

May, from the month in which it appears, has obtuse leaves, cut into three principal parts, and those serrate. True Azarole? has leaves like the foregoing, but larger, paler, and with broad lobes: the flowers and fruit are also much larger. All these you will find in your plantations: as you will also two trees that are in the third order, under the genus Sorbus; viz. the Sorbus. Mountain Albb and the Service; both which have pinnate or winged leaves, like the Ash: smooth on both sides in the first, but villous on the under furface in the fecond; these also have the lobes broader, and not so much serrated. Their common characters are—a quinquefid calvx, a pentapetalous corolla, and an inferior berry with three feeds.

The fourth Order (Pentagynia), besides the Apple, Pear, and Quince, comprehended under one genus, Pyrus, has the Medlar with many other species of trees or shrubs in a fecond ; and all the shrubs called Spiraea, in a third. These genera agree in a quinquefid calyx, and a pentapetalous corolla; the germ is inclosed within the flower in the last; but is beneath it in the rest:

<sup>\*</sup> Cr. Azarolus Lin.

B Sorbus aucuparia Lin. Mill. Illustr. Ger. 1473. Hunt Evel. Silva, p 211. Engl. Bot. 337.

Sorbus domestica Lin. Edw. av. t. 211. Ger. 1471. Engl. Bot. 350.

d Mespilus Lin.—germanica, Medlar Ger. 1453. 1. Blackw. 154.

the fruit is the principal distinction; in Pyrus it is a Pomum—in Mespilus a Berry—

in Spiraa a set of Capsules.

Mesembryanthemum.

This order boafts a large and splendid genus of herbaceous succulent plants, called Ficoides or Fig Marigolds. Fifty species all confent in a quinquefid calyx on the top of the germ; a multifid corolla of narnow linear petals; and a fleshy capsule divided into cells correponding with the number of styles, and containing many feeds. Though most of the species have five styles, vet some have only sour, and others have ten. This large genus is subdivided into three sections, from the colour of the flowers, which, being striking and permanent, may here very well furnish such a distinction, though it is in most cases a circumstance not to be depended on. The corollas, then, which are specious, very large, and double, are in the first section white, in the second red, and in the third yellow. The different forms of the fucculent leaves afford, almost of themselves. sufficient specific distinctions.

The most known species is that which is called Diamond Ficoides, or more commonly Ice Plant. This has ovate, alternate, waving leaves, with white corollas; but it is chiefly regarded for the singularity of be-

Mesembryanthemum Lin.

Mesembryanthemum crystallinum Lin. Dill. eth. t. 180. f. 221. Bradl. succ. 5. t. 15. f. 48.

ing covered with pellucid pimples, in the fun appearing like crystalline bubbles. Egrptian Kalis, esteemed for making the best pot-ash, is also of this genus; has alternate, roundish, obtuse leaves, ciliate at the base, and white corollas.

Of the last order of this class the Rose Rosa. is a genus univerfally known; and were it less so, would hold the first rank in the admiration of mankind. The distinctive characters are, a quinquefid calyx; a pentapetalous corolla; a kind of pitcher-shaped, fleshy berry, formed out of the calyx, terminated by the divisions of it, and containing several oblong, rough seeds, growing to the calvx on every fide. The species are distinguished by the globose or ovate form of the fruit, by the situation of the spines on the different parts of the shrub, the inflorescence, &c. The Sweet Briarh has globose fruits befet with crooked spines, and the leaves rubiginous or rusty underneath. The Dog-rose or Wild-Briari has ovate fruit, but smooth, as are also the peduncles; the

Mesem. nodisforum Lin. Mor. Hist. s. 5. t. 33. f. 7. Several species of this beautiful genus are figured in Mr. Curtis's Magazine:—as M. dolabriforme in t. 32.—bicolorum 59.—pinnatifidum 67.—barbatum 70.—pectabile 396.—aureum 262.—micans 448.—viridiflorum 326.—and many more in Dillenius's Hortus Elthamensis.

field however and the petioles are spinous, the petals are blush-coloured and bilobate, and there are two ciliate bractes, opposite

each other, to every flower.

Fragana. Strawberry, with all its various fruits, constituting only one species k is of this order. Here, though the corolla has only five petals, the calyx is cut into ten segments, alternately larger and smaller, and the seeds are dispersed over the surface of a roundish, pulpy receptacle, vulgarly called a berry. These are the generic characters. All the eatable Strawberries increase by runners; and by this circumstance they are sufficiently distinguished from the barren fort, which not only has a dry juiceless receptacle, but never throws out any of these runners.

#### THE CLASS POLYANDRIA.

The thirteenth class, Polyandria, has many stamens to the flowers m as well as the foregoing, but springing from the receptuale along with the pistil. These two classes united would have formed too large a class for commodious examination; a difficulty to be avoided certainly in all cases where we can; besides, the plants con-

Fragaria tterilis Lin. Curtis, Lond. III. 30. Ger.

m From 20 to 1000. " mil stamb & tranget ?

<sup>&</sup>lt;sup>1</sup> Fragaria vesca *Lin.* Mor. Hist. f. 2. t. 19. f. 1. Ger. 997. Bjackw. 77. 1.

tained in the one are in general so different, both in their form and qualities, from those of the other, that it would have been a pity to intermix beings so discordant, or to unite in the same class fruits which are so pleasant to the palate, and wholesome to the constitution, with herbs destructive to the human frame from their poisonous qualities; as many of those in the class *Polyandria* are known to be.

In the first order (Monogynia) you will Papaver. find the Poppy, which is sufficiently diftinguished by a calyx of two leaves, a corolla of four petals; and a one-celled capfule, crowned with the stigma, under which it opens with many holes, to give exit to the numerous little feeds. Of this genus, four species have rough, and five have fmooth capfules. The common Corn Popby; the species used in medicine, and which yields the Opium<sup>p</sup>; the Welch Poppy; and the Oriental fort, now introduced as an ornament to the flower garden<sup>q</sup>, are all of the latter division. The first has the capsules almost globose; the stalk covered with hairs, and fustaining feveral flowers of a fine high scarlet; and the leaves pinnatified and cut. The fecond

Papaver orientale Lin. Curt. Magaz. 57.

has the calvx smooth, as well as the capfule, the leaves cut and embracing the stalk: that which is cultivated in the fields has white corollas, and oblate spheroidal heads as big as an orange, with white feeds : the garden fort has purplish corollas, very dark at the base, with smaller oblong heads and black feeds: this varies much in com lour, and has fometimes very large and very double flowers, then resembling and immense Carnation. Some persons are of opinion that the Field and Garden Poppy are different species; Linnæus makes them but one: I have given you the differences, but do not take upon me to decide. The capfules of the Welch Poppy are oblong; the stalk smooth; the leaves winged and cut; the corollas large and yellow. The Oriental Poppy has rough leafy stalks, supporting one large, fingle, red flower; the leaves are winged, and ferrate about the edge. All the species of Poppy have a strong difagreeable fmell.

The Caper' is of this first order: so is the Tea-tree, and the Lime'; the Water-Lilies, both yellow and white, spreading

their broad leaves on the surface of slowmoving streams and stagnant pools, and
raising their ample many-petalled corollas
above it. Here also is the numerous and
beautiful genus Cistus, known by a calyx Cistus,
of sive leaves; two of which are less than
the other three; a corolla of sive petals;
and a capsule for a feed-vessel. Of these
there are forty-nine species, most of them
shrubs, but some herbaceous; the corollas
purple, white, or yellow, in the different
sorts.

Peony is of the second order, which is a Poonia. small one: the characters of the genus are—a calyx of five leaves, a corolla of five petals, and two or three germs, crowned immediately with stigmas, without the inter-

position of any styles.

This, and some plants of the following orders, are strictly united by one natural bond, under the name of Multifilique or Many-podded; having a fruit composed of several pericarps joined together. They agree likewise in having either no calyx, or at least one very apt to fall off; a polypetalous corolla, and stamens exceeding the petals in number. Of these you are acquainted with the Larkspur and Aconite, belonging to the third order; the Columbines to the fifth, and Hellebore to the last. None of them have any calyx; and they have all a corolla of five petals: the nectaries form the principal distinction of the general stress form the principal distinction of the general stress.

nium.

tum.

nera. This in Larkspur is bisid, sessile. and continued backwards into a horn or fpur. Aconite has two recurved, pedunculate nectaries. Columbine has five of these horn-shaped nectaries, between the petals. Hellebore has many short, tubulous nectaries, placed in a ring round the outfide of the stamens, each divided into two lips at top. Larkspur has also either one capsule or Delphithree, and the garden species is distinguished by its simple unbranched stem from the wild oney, which has it fubdivided: these both have the nectary of one leaf; in Bee Lark/pur and the rest it is of two. Aconite has the upper petal arched; and three or five capfules. You have one species common in your flower borders and plantations, with long spikes of large blue flowers, called Monk's-bood'; this is one of the species that have three capsules to a flower; and the leaves are multifid, with linear divisions, broadest at top, and marked with a line running along them. Wholesome Wolfsbane, as it is called, has five capfules,

five styles, and the flowers are sulphur-co-

loured.

<sup>4. 381.</sup>Aconitum Anthora Lin. Mill. fig. pl. 12. Jacq. auftr. 4. 382.

loured. Columbine has five diftinct capfules : Aquilethe common fort has bent necturies; in its gia. wild state the flowers are blue, the petals short, and the nectaries very prominent; in the garden you observe not only a variety of colours, but that the petals are excluded, and the nectaries much multiplied. Helle- Hellebobore has fometimes more than five petals to rus. the corolla; and always feveral capfules fucceeding to each flower: these contain many round feeds, fixed to the future of the capfule. The winter flowering species, commonly called winter Aconited, is the only one that drops its petals; it bears one yellow flower fitting on the leaf. True Black Hellebore or Christmas Rose, has one or two large white flowers upon a naked stalk, and fleshy pedate leaves. Stinking Black Hellebore, or Bear's foot fultains many greenish flowers on one stalk, and pedate leaves on the stem, but none towards the root. This is not uncommonly wild, and you will find it flowering during winter under the trees in your plantations. Caution your poor neighbours against being too free in giving their children this plant against worms; for in too large a dose it is certainly dangerous.

Helleborus fœtidus Lin, Blackw. t. 57. Ger. 976, 4. Engl. Bot, 613.

Indeed all the herbs just now described are more or less poisonous: Aconite is known

to be highly fo.

Lirioden- The last order of this class, Polyandria, dron. contains also the Tulip-tree, which has a triphyllous calyx, fix petals to the corolla, and many lance-shaped seeds lying one over another, and forming a fort of firobile. This tree is remarkable for the shape of its leaves, having the middle lobe of the three truncate, or cut transversely at the end. The flowers are large and bell-shaped; the petals" marked with green, yellow, and red spots. Here also are the Magnolias, which have a Magnolia. calyx of three leaves like the last, but a corolla of nine petals; the fruit is a strobile or fealy cone of bivalvular capfules, covering a club-shaped receptacle, each capsule con-

leaf and flower, will not bear all the rigour of our climate.

Anemone This order boasts two numerous general much esteemed among the storists—the Anemone and Ranunculus. The first has no calyx; a corolla of two or three rows, with three petals in each row: and many naked seeds, retaining each their style. You are now too far advanced in the science, to need a caution against taking the sine slowers.

taining a roundish seed, like a berry, hanging out by a thread. It is to be lamented that these sine trees, so beautiful both in

of

E Liriodendron Tulipifera Lin. Trew. Ehr. t. 10. Catesb. car. 1. t. 48. Curt. Magaz. 275.

of your beds, upon which the gardener for much values himself, in order to examine the corolla of the Anemone: they are the children of art; not those of nature, such as we are studying. The early Hepatica h is of this genus; and is known by its threelobed entire leaves. It is the only species which has any thing like a calyx; for it has a calyx of three leaves, which, being remote from the flower, is rather an involucre than a perianth. The Pasque flower i, so called from its flowering about Easter, is also of this genus: it adorns some of our dry chalky hills with its beautiful bell-shaped purple flowers; and though it has no calvx properly so called, yet the flowerstalk has a leafy multifid involucre; and the leaves are doubly winged, or bipinnate. Each plant bears but one nodding flower; but after that is past, the top of the plant is hoary with the tails, which adhere to the feeds. Another wild fort is the Wood Anemonek, bearing only one white or purplish flower on a plant; the leaves are compound, with cut lobes; and the feeds are pointed, but without tails. The Garden Anemones, which are so ornamental to the

h Anemone Hepatica Lin. Curtis, Bot. Mag. 10. Fl. Dan. t. 610.

Anemone Pulsatilla Lin. Relh. Fl. Cantab. p. 208. Fl. Dan 153. Ger. 385. 1. Engl. Bot. 51.

<sup>\*</sup> Anemone nemorosa Lin. Curtis, Lond. II. 38. Fl. Dan. 549. Ger. 383. 2. Engl. Bot. 355.

flower-garden in the spring, are only of two species, notwithstanding the great variety of their colours; red, white, purple. blue, with all the intermediate shades, and innumerable variegations of them. Art, to increase their beauty, has rendered them very large and double; but we can still diftinguish the species by their leaves, which in one are decompounded, dividing by threes; in the other digitate: the stalk is leafy; and the feeds are tailed, in both speeies.

lus.

Ranuncu. The rival genus of the Anemone is the Ranunculus, which differs from it in having a calvx of five leaves, and a corolla of five petals: but the diftinguishing mark of this genus is a honeyed gland just above the base of each petal, on the inside". Of forty-four species many are wild; and some extremely common in most parts of Europe, under the name of Butter-flowers, Buttercups, and King-cups. Three forts particularly, which at one featon cast a yellow veil over our meadows, are generally confounded and looked upon as one. However, the bulbous has the calyx bent back to the flower-stalk, whereas in the creep-

ing P and acrida it is open or spreading: in the first and second the peduncle is furrowed; in the third it is round, without any channelling; besides this, the leaves are very different upon inspection; and the first has a bulbous root, the second throws out abundance of runners which strike root like those of the strawberry, and the third is a taller, genteeler, later-flowering plant. But not the meadows only are filled with Ranunculi; the woods, the corn-fields, the waterst, have also their share of them. One species, which flowers in moist meadows very early in the spring, is so diftinct from its fellows, that some Botanists have not scrupled to remove it from this genus, to form one by itself; for it has a calvx of three leaves only; but, to make amends, a corolla of more petals than five: it has heart-shaped, angular, petiolate leaves, one flower on a stalk,

# LETTER XXII.

#### THE CLASS DIDYNAMIA.

July the 1st, 1775.

AVING now finished more than half our course, we are arrived at a set of natural classes, with which you are so well acquainted, as to find no difficulty in assigning the proper place to any plant

belonging to them.

福度 計 湯

The structure of the flowers in the four-teenth class was explained at length in the fourth letter: but the proper and essential character of it is, the having four stamens, all in one row, and in pairs; the outer pair longer than the other, whence the name Didynamia; and one style: all included within an irregular monopetalous or ringent corolla.

This class has only two orders; which are not founded upon the form of the flower, as you might be led to suppose from what was said in a former letter; nor upon the number of the styles, as in the foregoing classes, because none of the flowers have more than one; but upon the circumstance of having four naked seeds, bosomed in the calyx; or else many fixed to a receptacle in the middle of a pericarp: the first

ma.

of these is called Gymnospermia, the second

Angiospermia.

This class contains one hundred and two genera, and fix hundred and forty-three species; and each order forms a natural one—the first including the Verticillate plants, fo called from the manner in which the flowers grow, in verticilli or whorls: they also agree in producing the leaves by pairs, and in having the stalks square. The fecond comprising the Personate flowers; or fuch as have mostly a personate corolla, but always a pericarp, or veffel inclosing the feeds.

#### THE ORDER GYMNOSPERMIA.

The effential generic character of Ground Glecho-Ivy is at the same time beautiful and extremely distinctive, each pair of anthers forming an elegant little cross, one above the other. The leaves are kidney-shaped, and notched about the edges. In this genus, in Hyssop, Mint, Lavender, Bugle, Betony, Dead-Nettle, Cat-Mint, Savory, Horehound, &c. the calyxes are pretty regularly quinquefid. In Thyme, Banl, Self-heal, Marjoram, Baum, &c. they are bilabiate. In Mint the corollas are hardly ringent: the filaments are straight and diftant. Lavender has the corollas, as it were,

w Clechoma hederacea Lin. Curtis, Lond. II. 44. Ger. 856. 1. Pl. 20. f. 1. of this work, & Fl. Rust. t. 61. turned

turned topfy-turvy; that which is the upper part in most others being the lower in this, and vice versa: the calyxes also are supported by a bracte; and the stamens lie within the tube. Teucrium has no proper upper lip, but the corolla is slit quite through for the stamens to pass. Bugle has Ajuga. the upper lip of the corolla remarkably short, much shorter than the filaments: our common wild species\* is known by its fmoothness, and increasing by runners. Be-Betonica. tony has the upper lip of the corolla flattish and rifing, with a cylindric tube; the fegments of the calyx are prolonged into narrow thin points like awns; and the filaments extend not beyond the neck or opening of the tube. Wood Betony y is distinguished by an interrupted spike, and by the middle segment of the lip being emarginate, or having one notch. Cat-mint has the middle divi-Nepeta. fion of the lower lip crenate, or flightly notched; the edge of the chaps reflex; and the stamens close. The flowers of the wild species 2 are in a spike, consisting of a fet of whorls on short peduncles; the leaves are heart-shaped, bluntly serrate and petiolate. If you have any doubt concerning this

X 2 plant,

plant, present it to puss, and she will inform you by the caresses which she bestows upon it, in common with Marum and Valerian; the first of which not growing wild, and the fecond being so very different a plant, she cannot lead you into an error. Black Hore-Pallota. bound and White Horehound both have a calyx marked with ten streaks; but the upper lip of the corolla, in the former, is arched and crenate: in the latter straight, linear, and bifid. Common Black Horehound is known by its whole, heart-shaped, serrate leaves, and sharp-pointed calyxes; the corollas are red. Common White Horehound Marruhas the divisions of the calvx ending in febium. taceous hooked points: the corollas are white, and the whole plant has a white appearance from the nap that covers the Stalks; and leaves.

Thymus Of the fecond division with bilabiate calyxes, Thyme has the opening of the tube closed with hairs. Wild Thyme' that smells fo gratefully, and adorns dry sheep-pastures with its red flowers, is known by these flowers growing in a head; by the divisions of the calvx being ciliate: the leaves ovate, flat, blunt at the end, dotted with little

glands,

glands, and ciliate at the base; and by its creeping stalks. Garden Thymed is an erect plant, with its ovate leaves revolute, and the flowers in a fet of whorls, all together making a spike. Of this there are several varieties, as there are also of the other. Basil has an involucre of many narrow leaves immediately under the whorl of flowers. Marjoram is distinguished by an involucre Origacomposed of ovate, coloured, imbricate num. bractes, forming all together a square kind of spike or strobile. Wild Marjorame has the spikes rounded at the corners, conglomerate, and all together forming a panicle; the bractes longer than the calyxes. You will find this wild under hedges and among bushes. That which is in the kitchen garden, under the name of Pot Marjorami, differs not greatly from the next: the spikes are oblong, aggregate, and hairy; the leaves heart-shaped and nappy; the stem woody, and the flowers white. Sweet Marjorams has ovate leaves, blunt at the end, and roundish compact pubescent spikes. Winter Sweet Marjoramh has long, aggregate, pedunculate spikes, and the brackes the length of the calyxes. The corollas of this are

white; of the other red. Dittany of Crete<sup>2</sup> has the small purple flowers collected in loose, nodding heads, with imbricate bractes; the stalks are pubescent, purplish, and send out small branches from their sides by pairs; the leaves are round, thick, and so woolly as to be quite white: the whole plant has a piercing aromatic scent, and biting taste. This is the celebrated plant with which Venus cured the wound of Æneas\*. Baum has a dry, chaffy, angular calyx, slattish at top; the upper lip rising: the casque of the corolla is a little arched, and deeply notched or bisid: the lower lip is trifid, with the middle lobe heart-shaped.

Melissa. Common Garden Baum<sup>1</sup> has the flowers growing in small loose bunches from the wings of the stalk, in whorls; and the pedicles are simple or unbranched. There are two plants of this genus growing wild, that

Dracoce-have the name of Calamint. Dracocephalum phalum is distinguished principally by the great inflation, or wide opening of the chaps of the corolla; the upper lip also is arched, folded, and obtuse. Of this genus is the very fine-smelling plant vulgarly called Baum of Gilead, which has compound

leaves, confisting of three or five oblong, pointed, ferrate leaflets; and flowers coming out in thick, short spikes: the corollas are pale blue. Self-heal is known immedi-Prunella. ately by its forked filaments, with the anthers inferted below the top: the stigma also is emarginate or bifid. Wild Self-healo, fo common in pastures, has all the leaves of an oblong ovate form, ferrate about the edge, and petiolate. Scutellaria is abund-Scutellaantly distinct from all the other genera of ria. this order by its fructification; for the calyx is entire at the mouth, and, after the flower is past, closes with a kind of lid: so that the whole bears a refemblance to a helmet, whence the names of Cassida, Skull-cap, and Hooded Willow-herb: and the feeds being hereby inclosed in a kind of capfule, this genus forms the connecting link between this order and the next. The species common on the banks of rivers, by ditch fides, and other watery places p, has lance-shaped leaves, hollowed at the base, notched about the edge, and wrinkled on the furface; the flowers are blue, and proceed from the axils, or angles formed by the leaves or subdivisions of the main

#### THE ORDER ANGIOSPERMIA.

The corollas in all the genera of the first order, with very few exceptions, are openmouthed, Labiate, or Ringent, properly fo called. In the fecond order, which you are now going to furvey, many of them are Personate, or Labiate with the lips closed; some however have open bell-shaped, wheel-shaped, or irregular corollas. To have feeds inclosed in a Pericarp is common to all, and hence the name of the order Angiospermia. In most of the genera the calyxes are quinquefid; in some however they are bifid, in one trifid, in many quadrifid, and in two multifid.

che.

Of those with bifid calyxes, you have Oraban- the Orobanche or Broom-rape; which has an open corolla, divided at top into four fegments, and nearly regular; there is a gland at the base of the germ; and the capsule is unilocular and bivalvular. The common species q has a pubescent stalk, absolutely undivided; the fingular feuillemort hue of this plant is alone sufficient to betray it to you at first fight.

Among such as have quadrifid calyxes, Rhinan- are Rhinanthus, Yellow Rattle, or Cock'sthus. comb, and Eyebright: these have Personate

> Orobanche major Lin. Curtis, Lond. IV. 44. Ger. 1311. 2. Engl. Bot. 421.

corollas:

corollas: the first has the calyx swelling; and an obtufe, compressed bilocular capsule. The wild fort r, common in moist meadows, is known by the shortness and compressed form of the upper lip of the corolla; the colour is yellow: the calyx is very large; being an early flowering plant, this part grows dry before the time of mowing, and makes a crashing or rattling found under the scythe. Euphrasy, or Eyebright, once cele- Euphrabrated as fit "to purge the vifual ray," fia. has the calyx cylindric; the anthers spinous at the base of one of their lobes: and the capfules of an oblong ovate form, and bilocular, The officinal species has ovate linnear leaves, sharply indented about the edges. It is an humble, neat plant, growing in dry pastures and heaths; and the corolla, on a near view, is very elegant.

In the largest section, with quinquesid ca- Antirrlyxes, you will find the Antirrhinum genus hinum. comprising forty-seven species. The corolla is personate, prolonged at the base into a

lar capsule. Of two species formerly mentioned to you, Toadflax has linear leaves inclining to lanceolate, growing many toge-

bag or spur; and the seed vessel is a bilocu-

ther

<sup>&</sup>lt;sup>r</sup> Rhinanthus Crista galli *Lin*. Curtis, Lond. V. 43. Engl. Bot. 657. Mor. Hist. s, 11. t. 23. f. 1. Ger. 1071. 1. Fl. Rust. 138.

t Antirrhinum Linaria Lin. Curtis, Lond. I. 47. Ger. 550. 1. Fl. Rust. t. 93. Engl. Bot. 658.

ther upon an erect stalk; the flowers grow close in sessile spikes, terminating the stem; the under lip of the corolla is hairy within, the chaps are orange-coloured, but the rest is of a pale yellow, and it ends in a long spur. It is now in flower, or will foon be fo. Accident has produced a strange variation in this plant, by changing the corolla from personate with four didynamous stamens, to regularly pentapetalous with five, the rest of the plant remaining the same". Varieties partaking of the nature of two species are not uncommon'; but as they are generally found among annual plants, and never produce feed, they are lost almost as foon as they come to perfection. Whereas this being perennial, and creeping much at the roots, has been preferved as an example of monsters in vegetable nature. Snapdragon w has the leaves of the calyx rounded at top, the flowers growing in a spike, and the corollas spurless; the colours of these are red with white or yellow mouths, or entirely white, or elfe white with yellow mouths: the leaves are lance-shaped and petiolate. Several species of Antirrhinum are wild on walls and in corn-fields: and feveral others are not uncommon in gardens:

<sup>&</sup>quot;This is described at length under the name of Peloria in the first volume of Immen. Acad. and is elegantly figured by Dr. Thornton, and in Curt. Magaz.

These are called Hybridous plants, or Mules.

W Antirrhinum majus Lin. Mill. fig. t. 42. Ger. 549. 1, 2, 3. Engl. Bot. t. 129.

as Three-leaved Toadflax\*, an annual plant, having ovate, smooth, gray leaves, generally ternate, as the name implies, but sometimes only in pairs: the flowers grow in short spikes at the top of the stalks, and are shaped like those of common Toad-slax, only the tubes are not so long; they are yellow, with saffron-coloured chaps. Two or three perennial species with handsome spikes of blue slowers, and some of them smelling sweet, are usually in large borders, among slowering shrubs, and other perennials.

Scrophularia or Figwort is another of Scrophuthese; the corolla is of the topsy-turvy kind, laria. almost gobular in its form; the two upper divisions are the largest and erect; the two side ones spread open, and the sisth below is reslex. In many species, under the topmost division, in the chaps of the corolla there is a little slap resembling a lip: the slower is succeeded by a bilocular capsule. Two species are sufficiently common: one in woods and hedge-rows, with the angles of the stem blunted, and heart-shaped leaves, much prolonged at the tip, and marked with three rising nerves; the other by river

fides, and in other watery places with a membrane running along the stalk at the angles, and heart-shaped leaves blunted at the end. These plants have a dusky shade spread over their green, and their flowers are of a dull red.

Digitalis. Foxglove, one of the most showy of our wild plants, has an open corolla, divided into four segments at top, and swelling out below, shaped like the singers of a glove; the capsule ovate and two-celled. Wild or purple Foxglove b is distinguished by having the leaves of the calyx ovate and acute, with the segments of the corolla obtuse, and the upper lip entire: the inside of the corolla is beautifully sprinked with spots resembling eyes; and the leaves are large and wrinkled: red is the colour of the flower in its wild state; when cultivated in gardens it varies to white and yellow.

Bignonia Bignonia has a cyathiform calyx, narrow at bottom, and spreading wide at top; a bell-shaped corolla, swelling out below, and divided into five segments at top; and a two-celled slique for a seed-vessel, containing winged seeds lying close over each other. The Trumpet-slower of Virginia and Canada, with its trailing branches, putting

<sup>&</sup>lt;sup>2</sup> Scrophularia aquatica Lin. Curt. Lond. V. 44. Fl. Dan. 507. Blackw. t. 86. Ger. 715.

<sup>&</sup>lt;sup>c</sup> Bignonia radicans Lin. Mill. fig. pl. 65. Pl. 20. f. 2.

out roots from the joints, to acquire support and nourishment from trees, has pinnate leaves, the leaslets of which are cut: the large trumpet-shaped flowers are orange-coloured. The Catalpa<sup>d</sup> is a great tree with leaves remarkably large, simple, and heart-shaped: the flowers are produced in great branching panicles: they are of a dirty white, with a few purple spots, and faint stripes of yellow; but what is most singular, they have only two perfect stamens, with small rudiments of three others; the calyx is also not barely quinquesid, but divided quite to the bottom.

Acanthus, the leaves of which are faid to Acanhave given the first hint of the elegant Co-thus-rinthian capital, is also of this order, but of that section which has bisid calyxes: it has an irregular corolla, without any upper lip; the lower one has three lobes; the anthers are villous, and the capsule is two-celled.

I cannot help remarking to you, fince it has struck me, that the greater part of the genera in the principal section of this order, is dedicated to the memory of eminent botanists. Here stands the great Linnæus himself; the celebrated Arabian Avicenna; those fathers of the science Gesner and Columna: in Italy, Crescentio, Tozzi, Vandelli, Durante, Cirillo; the illustrious Frenchmen,

d Bignonia Catalpa Lin. Duham. arb. 1. t. 41. Catesb. ear. 1. t. 49.

Bignon,

Bignon, Barrelier, Ruellius, Cornutus, Dodart: Celsius, Toren, Brovall, Swedes: Brunfelfius, Buchner, Bontius, Volkamer, Loesel, Bester, Hebenstreit, Lindern, Gmelin. and other Germans; Oviedo the Spaniard; and of England old venerable Gerard, Millington, and, in more modern times, Lord-Petre and two contemporary professors of Oxford and Cambridge. The illustrious, the indefatigable Baron Haller occupies a fection alone, as he well merits, being himself an host. This plan, of consecrating newly discovered plants to perpetuate the memory of persons who have been eminent in the science, appears to me well imagined. Ladies have had this honour, as well as the men; and I have no doubt, dear cousin, but you will one day merit a niche in this temple.

## LETTER XXIII.

#### THE CLASS TETRADYNAMIA.

August the 4th, 1775.

DEFORE any idea of system or arrangement had gone abroad, every scientific eye perceiving a fimilitude between the Cabbage and Turnep, the Stock and Radish in the fructification, there was an universal agreement among authors to place thefe plants, and others like them, in the same fection or division of their books, and to treat of them all together. You have already seen the nature of this similitude, and are not at any loss in classing the Cruciform tribe: you have only to learn that the fifteenth class (Tetradynamia) in the system of Linnæus, contains the same plants as you have been accustomed to call Cruciform; and to recollect that it has the long Greek name from four of the stamens being more powerful or longer than the remaining two; the circumstance on which Linnaus founds the character of the class; and which distinguishes it from the fixth, wherein the fix stamens are of equal length, or at least not of that regular, proportional inequality that we discover in the class now before you.

It will suffice to examine a few of the genera and species, which are not extremely numerous, and therefore my present letter will not extend to that frightful length that some of the former have done.

#### THE ORDER SILICULOSA.

The Siliculofe or short-podded order leads the way, and is subdivided into two sections; the first containing those which have the filicle entire, and the fecond such as have the filicle notched at top. From the first subdi-Lunaria, vision I shall select Honesty for your observation, because it is common in gardens, and has larger parts than most of these flowers. The filicle is oval, entire, quite flat, and stands on a pedicle; the valves are equal to the partition, parallel and flat: the leaflets of the calyx are bagged. The brilliant whiteness of these silicles has occasioned this plant to be called White Sattin: and from the shape of them it is named Lunaria and Moonwort. Linnæus mentions but two species; the annualh differing from the bienniali in having larger flowers of a lighter purple, and the pods longer and narrower: they have both heart-shaped leaves, indented on their edges, are a little hairy, and end in

acute

<sup>\*</sup> The genera are 32, and the species 287.

h Lunaria annua Lin Mill. Illustr. Besl. eyst. 7. f. 1.

<sup>1</sup> Lunaria rediviva Lin. Beil. eyit. 7. f. 2.

acute points; the lower ones are on long petioles, but the upper ones fit close to the stalk.

Of the fecond subdivision is the Candy Iberis. tust or Iberis, known by an irregular corolla with the two outer petals larger than the two others. Red Candy-tust is an annual herbaceous plant with red flowers growing in a kind of umbel; your gardener sows it in patches about the borders of your flowergarden; it has lance-shaped leaves drawn to a point: the lower terrate, the upper ones quite entire: the flowers of this are sometimes white, and then it is consounded with the bitter species, which however has the leaves not so sharp-pointed, and with only few indentations: the flowers also grow in a raceme, and the plant is more branched.

In this subdivision also ranges Scurvy-Cochleagrass and Horse-radish, agreeing in a heart-ria. Shaped, turgid, rugged silicle, the valves of which are gibbous and obtuse. Officinal or Garden Scurvy-grass has a branching stalk; the lower leaves rounds than hollowed next the petiole; the stem-leaves oblong and substitutions: the white flowers are produced in clusters at the ends of the branches. English

Sea Sea

<sup>&</sup>lt;sup>k</sup> Iberis umbellata Lin. Riv. tetr. 225. Curt. Mag. 106.

m Cochlearia officinalis Lin. Fl. Dan. 135. Ger.
401. 1. Engl. Bot. 551.—Danica, 696.

Sea Scurvy-grass has longer leaves, and all of them finuate. Horse-radish, which sew besides Botanists observe in slower, has the radical leaves lance-shaped, and notched about the edges, the stem-leaves gashed.

### THE ORDER SILIQUOSA,

The fecond order, containing the Cruciform flowers, succeeded by a silique or long pod, is also subdivided into two sections; in the first of which the leaflets converge at top, in the fecond they gape. Radish, Erysimum, Stock, Wall-flower, Rocket, Arabis, Cabbage, Turnep, &c. range in the first section: Woad, Sea-Colewort, Cardamine, Mustard, Charlock, Water-Cress, &c. in the second. Radish has a cylindric, jointed, torose or swelling silique; and one pair of glands between the shorter stamens and the pistil, with a second pair between the longer stamens and the calyx. Ervsimum has a columnar filique with four equal fides. Of this there are feveral wild species: as, first, the common?, growing by road fides, well diffinguished by its runcinate leaves, and filiques pressed close

to the stalk: secondly, Winter Cress 9, with lyrate leaves, the outmost lobe roundish, and spikes of yellow flowers, growing by ditchfides: and thirdly, the garlick-finelling, called thence Sauce-alone, and, from the utual place of its growth, Jack-by-the-hedger, has heart-shaped leaves: the flowers are white,

'but the smell betrays it at once.

Stock Gilliflower and Wall-flower have two Cheiranleaflets of the calyx gibbous at the base; the thus. germ has a glandular toothlet on each fide; and the feeds are flat. The two species are thus diffinguished. Wall-flower' has acute, smooth leaves, with angular branches. Stock has obtuse hoary leaves, with flatted filiques truncate at top: both have shrubby stems, and lance-shaped entire leaves. The Annual or Ten-week Stock u differs in having an herbaceous stalk, the leaves somewhat toothed, the petals notched, and the filiques cylindric and acute at the end. Rocket has the petals obliquely bent; a gland on each fide within the shorter stamens; the stigma forked, with the parts converging at top; and the filique stiff and upright.

Arabis has four glands, within the leaflets of the calyx, like reflex scales. Some of the species are wild w, and the Alpine fort is now common in many gardens: the leaves of this embrace the stalk, and are toothed about the edges; it bears white

Braffica. flowers in loofe corymbs, cabbage, Turnep, Coleseeda, &c. all agree in having the glands disposed as in the radish; the leastets of the calyx are erect: the claws of the corollas hardly fo long as the calvx; the filique is roundish, a little flatted on each side, with the valves shorter than the partition; and filled with feveral globole feeds.

Ifatis.

Of the fecond fection, Woad, has a lanceshaped, bivalve, one-celled filique, containing one feed only, and deciduous; the valves are boat-shaped. The species cultivated for dyeing b has the radical leaves notched and petiolate; the stem-leaves sagittate, or shaped like the head of an arrow. and embracing the stalk; and oblong filicles, It is a large plant, with corymbs of small Crambe. yellow flowers. Sea-Colewort has a globose

> \* Arabis thaliana, Curtis, Lond. II. 49. ffricta. Engl. Bot. 514. Turita Lin. Jacq. austr. t. 11. Engl. Bot. 178.: but the last has glands as in Prassica.

duous, and contains one feed; but its most remarkable character is, that the four long filaments are forked at the end, and the anthers are borne on the outer forks. Our species c has the stalk and leaves smooth.

Cardamine, Cuckow-flower or Lady's Smock, Carda-(forgive the vulgar name) has the calyx mine. gaping a little: two glands, one on each fide, between the shorter stamens and the calyx; and an elastic filique, the valves rolling back with force when the feeds are mature, and thus throwing them off to some distance. There are many species wild: but that which is common in moist meadows, and on the banks of brooksd, has pinnate leaves, the folioles on the radical leaves roundish, on the stem-leaves lance-shaped. The allusions to the whiteness of the corollas will not hold, for they are commonly purple.

Mustard has the claws of the corollas Sinapis. strait, and the glands as in the Cabbage genus, to which it is very nearly allied; differing from it only in the circumstance first mentioned, and in having the leaslets of the calyx spreading: the filique indeed is different; being torose and rough, with the partition usually very long; but this is reserved for the specific distinction. The

Crambe maritima Lin. Fl. Dan. 316. Ger. 315.

<sup>15.</sup>d Cardamine pratensis Lin. Curtis, Lond III. 40.
Ger. 259. 1, 2. Fl. Rust. t. 95.
wild

wild species, a weed so common among corn, and generally called Charlocke, has many angled, torose, smooth filiques, longer than the two-edged beak. Black or Common Mustard has smooth siliques pressed to the raceme, or common bunch of the fructification. White Mustards has the filiques hifpid, terminated by a very long, oblique, fword-shaped beak. If you suffer some of the plants which your gardener fows for small fallad to grow up and flower, you will find it to be the last-named species. Common Mustard is a much larger plant, growing four or five feet high; the lower leaves large and rough, like those of the Turnep. Charlock does not grow more than two feet in height; the leaves which are also rough, are sometimes jagged, and sometimes entire.

Sifymbrium.

Water-Crefs is of a numerous genus, there being twenty-nine species of Sifymbrium. The corolla is spreading as well as the calyx in this genus; and the silique gapes with straightish valves. The specific characters of Water-Crefs are, short declining siliques, and pinnate leaves, with the

lobes

Sinapis arvenfis Lin. Curtis, Lond. V. 47. Fl. Dan. 753. Mor. Hift. f. 3. t. 3. f. 7. Ger. 233. 2.
 Fl. Ruft. t. 101.

h Sifymbrium Nasturtium Lin. Curtis, Lond. II. 61. Fl. Dan. 690. Ger. 257. 1. 2nd pl. 21.

lobes a little heart-shaped. The flowers are white, and grow in a corymbi. There is another species, called Flixweedk, not uncommon on dunghills, where rubbish is thrown out, by way-sides, and in uncultivated places: this has decompound pinnate leaves, and very small corollas, the petals being less than the calyx: the silique is very long and slender, filled with small roundish seeds: the leaves are as finely cut as Roman Wormwood; and the small yellow flowers are produced on loose corymbs, at the top of the stalks.

The season, dear cousin, is now in its wane, and a journey I must make, on affairs of business, obliges me to leave the completion of my plan to another summer. If leisure and health are then granted me, I shall with pleasure resume the employment which you honour with your attention. In the mean time you and your fair daughter have enough to amuse you for the autumn, and even till winter confines you to the arrangement of your summer's labours within.

# LETTER XXIV.

### THE CLASS MONADELPHIA.

June the 1st, 1776.

COME necessary occupations, dear couin have prevented me from refuming my pleasing task so soon as I had wished. But the fpring has not been unprofitably employed by you, in the examination of fuch plants as were past flowering before you received my former letters. You have done well by marking in your pocket-book the names of all those which have either wholly escaped your search, or have prefented themselves to you in a state unfit for complete examination. You are not fo unreasonable as to expect that all Nature should be open to your view at once. On the contrary, I am charmed with your patience and affiduity in awaiting the proper feafons of flowering and fruiting; marking the times which authors have let down; and repeating your examinations in order to view plants in their different states, when they sometimes put on appearances so different, that to a less informed eye they might feem to be distinct species.

We are now arrived at a class, of which you have had no previous information in the introductory letters, designed to give

you a general knowledge of the most natural. The class Monadelphia however is a natural, as well as a most beautiful one. The union of the filaments at bottom into one body, or brotherhood as it were, is the leading character, and the occasion of the name. You will recollect that hitherto the stamens have been ever free and distinct from each other, how many foever you may have found in a fingle flower; you will also recollect having been informed, that in the fixteenth and fucceeding classes, they are united, either at top or bottom, into one body or more. In this, as I observed before, the filaments all join below, next the receptacle, some higher than others; all of them, together with the anthers, being still entirely separate at top.

If then you have met with a plant which has five, ten, or especially many stamens, and you have not been able to affign it a place in the fifth, tenth, or thirteenth classes, examine it a little more attentively, and confider whether it has not a peculiar part or structure, announcing it to belong to a natural tribe. It may perhaps have a permanent calyx; but if it is also double, you may be almost certain that it ranges here. The corolla of your flower may perhaps have five heart-shaped petals, the side of one embracing or at least touching that which is next to it, in a direction contrary to the fun's apparent motion. The filaments, perhaps,

haps, connected at bottom only, whether flightly, or for a confiderable portion of their lengths, are gradually shorter as they recede from the middle; and the anthers are incumbent, or lie along over the top of them. You find the receptacle of the fructification prominent in the centre of the flower; the top of this receptacle furrounded by erect germs forming a jointed ring: all the styles united below into one body with the receptacle; but distinguished at top into as many filaments as there are germs: these germs becoming a capfule confifting of as many cells as there are pistils in the flower: and frequently confifting of as many connected Arils. In each of these cells lurks a kidneyshaped seed.

If you have not already divined this riddle, take the flower of a wild Mallow, an Althæa, Lavatera, or other plant refembling these; examine it by the characters just laid down, and you will have a perfect idea of the class *Monadelphia*. From the circumstance of the receptacle standing up in the middle of the flower, like a column, these have also the name of columniferous plants.

The orders are five, taken from the number of the stamens, which you remember determined the class in the first thirteen classes; but, being now no longer used for that purpose, may serve very well for the

other.

The fruit was formerly taken for discriminating the genera. This being found insufficient, succeeding nomenclators had recourse to the leaves; but Linnæus has, for this purpose, wisely adopted the calyx, which is always present, and is remarkable for its structure in this class. The illustrious Swede has ever shewn great sagacity in seizing that part of the plant which is most constant, and surnishes the greatest choice of permanent variations, whereon to found the essential characters of his general and species.

## THE ORDERS PENTANDRIA AND DECANDRIA.

Not having taken the pistil for the distinction of the orders, that part remains to assist us in characterising the genera. Accordingly in the first order of this class, in which the flowers have five stamens, two genera have one, and two have sive styles; the number of cells in the capsules ferves to complete the generic character. Thus Hermannia has sive styles, and a five-Herman-celled capsule; to which we may add, that nia. the five petals of the corolla are rolled spirally in a direction contrary to the sun's apparent motion; and that their claws have

Genera 35, and species 256, in this class.

a little membrane on each fide uniting to form a cowled tube. Though there are many species of this genus, yet perhaps none of them may offer themselves to your view. We will proceed therefore to a favourite genus, that ranges in the fecond order, or that which has ten stamens: I mean Geranium, which, out of its eightytwo species, will furnish you ample matter for examination, especially as I know you cultivate so many of them. Before you determine the circumstances in which they differ, let us fee in what they all agree; this is, in having one style terminated by five stigmas; and a fruit composed of five grains, and beaked: whence its names of Geranium and Cranesbill. We may add that the calyx is fingle and five-leaved, as well as the corolla; that the filaments are alternately longer and shorter, but all shorter than the corolla, and very flightly connected in those which have a regular corolla; that the style is longer than the stamens, and permanent; and that each of the five feeds is terminated by a tail or awn, affifting to form the beak, and which when the feed is ripe becomes spiral, and thus detaches the seed from the plant.

The African species, of which we have fo many from the Cape of Good Hope, have the five parts of the calyx united at bottom; the petals unequal; and feven only of the filaments furnished with anthers;

Geranium. the flowers grow many together in a kind of umbel; the feeds are naked, with a feathered awn, and the leaves grow alternate

upon the stalk, which is shrubby.

In this first section you find, among many others, the Fulgid<sup>m</sup>, with a sleshy stem, putting out but sew branches; the leaves three-parted and gashed, the middle segment much larger than the others; frequently falling off, so as to give the stalks an appearance of being dead during the summer; the slowers are produced on short sootstalks, in a fort of double umbel, each sustaining but two or three slowers, remarkable for their deep shining scarlet colour.

The well known Scarlet<sup>n</sup>, which would be at least as much esteemed as the Fulgid, were it not more common. The leaves are almost orbicular, except that they are hollowed next the petiole; they are notched about the edge, but not gashed or lobed: their surface is downy; and they stain the singers if handled roughly, whence the trivial name of inquinans or staining. This is a much lostier plant than the last, growing as high as eight or ten feet; and sends out abundance of erect branches: the slowers in the umbels are numerous, and are produced on very long peduncles.

m Geranium fulgidum Lin. Dill. elth. t. 130. f. 137.
n Geranium inquinans Lin. Mill. Illustr. Dill. elth.
t. 125. f. 151. Mart. cent. 3.

The Papilionaceous, fo called, because the corollas have something the appearance of buttersly or pea-blossom slowers, the two upper petals, which are large, turning up like the banner or standard in those slowers; these are finely variegated, but the three under petals being reslex and small are scarcely observed, but on a near inspection; the slowers are many in each umbel: the leaves are large, angular, rough, and stand on long petioles.

The Hollow-leaved has roundish leaves contracted on the sides so as to stand hollow; the edges are sharply indented; the flowers are large, and produced in loose umbels; the corollas are purple: it is a plant of considerable stature, and very hairy.

There is another fort, or variety, very like this; but it has leaves of a thicker sub-stance, and divided into several acute angles; the branches are not so irregular, and the bunches of flowers are not so large.

The Horse-shoe q is perhaps the specie most commonly known of all the Africans; the dark or purplish mark, in shape of a horse-shoe, upon the leaves, shows this Geranium to the eye at first sight: but it is

Geranium papilionaceum Lin. Dill. elth. t. 128. f. 155. Mart. cent. 15.

P Geranium cucullatum Lin.—cowled. Dill. elth.

t. 129 f. 156. Mart. cent. 28.

Geranium zonale Lin. Comm. præl. 51. t. 1.— See the flower in pl. 22. f. 3.

not absolutely permanent; for we have varieties without it: we must have recourse therefore to the form of the leaves, as a more certain distinction: they are orbicular, hollowed next the petiele, divided on the circumference into several obtuse segments, each of which is slightly indented. This sort is very branching: the flowers are produced in large, close umbels, on long peduncles, and vary from a light purple to a high scarlet.

The Vine-leaved has ovate afcending pubescent leaves, having the smell of Baum when rubbed; the slowers grow in a close head, on long peduncles, rising much higher than the branches; they are small, and pale

blue.

The Rose-scented has also lobed leaves, waved and villous; like the last, the flowers grow in close heads; they are of a purplish blue: the branches are very irregular and weak: and the whole is weaker and grows taller than the former; the leaves when rubbed smell like dried roses.

The plants of the second section have many things in common with those of the first; but differ in being herbaceous, and having the leaves opposite. Of these the Odorous' is remarkable for its powerful seent,

fomething

Geranium vitifolium Lin. Dill. elth. t. 126. f. 153.

Geranium capitatum Lin. Riv. pent. 326.
Geranium odoratiffimum Lin. Dill. elth. t. 131.
Lin. 138.

fomething like Aniseed: this has a very short sleshy stem, with long branches, and heart-shaped leaves extremely short: the slowers are produced from the side of long prostrate stalks, upon slender peduncles, three, four, or sive together; they are

white, and very fmall.

The Night-scented has fessile calyxes, and bissid one-leased scapes: the leaves are hairy, and almost as finely divided as the carrot; the stalks are about a foot high, and have two or three smaller leaves that are sessile; hence arise two or three naked peduncles, terminated by an umbel of yellowish slowers, marked with dark purple spors, smelling very sweet after sun-set. Linnæus has taken his trivial name from the dulness of the colour in the slower.

The third fection contains such Geraniums as have only sive of the stamens anther-bearing; sive-leaved calyxes, and fruits hanging down. The corollas of these are less irregular; and the seeds are naked, terminated by a hairy awn.

Of this fection we have fome European species, as Hemlock Cranesbill, common in sandy soils: this has a branching stalk, pinnate leaves, with the segments gashed and obtuse, and many slowers on a peduncle.

<sup>&</sup>quot;Geranium triste Lin. Com. can. t. 110. Breyn. cent. t. 58.

Ger. 945. 3.

Very like this is Musk Cranesbill", but it is a larger plant, much less common, and easily known by its musky odour: the divisions of the leaves are pinnatifid. Some species\* of this fection are remarkable for the largeness of their beaks, and furnish a good idea

of the name of the genus.

In the three remaining fections, all the ten filaments are topped with anthers; the calyxes are five-leaved; the corollas regular; the feeds covered with an aril, and terminated by a smooth awn. In the fourth fection, the flowers are conjugate; that is, there are two always on every peduncle:

the plants are perennial.

Some of the largest and handsomest of the European forts range in this fection; as Spotted Cranesbilly, with the peduncles and leaves alternate, the calyxes a little awned, the petals waved, and the stem erect. The leaves are divided into five or fix lobes, laciniate on their edges; those near the root fit on long petioles, but on the upper part of the stalk they are sessile. The flowers are of a dark purple. There is a variety of this with light purple corollas.

Meadow Cranesbill has the leaves divided

w Geranium moschatum Lin. Riv. pent. 110. Ger: 941. .8 0 .

<sup>\*</sup> Geranium arduinum, gruinum, ciconium Lin.

into fix or seven lobes, cut into several acute segments; they are wrinkled, and rather peltate; the petals are entire, and of a fine blue.

The Geraniums of the fifth fection differ from those of the fourth only in being annual. Most of the common European sorts are of this division: as Herb Robert<sup>2</sup>, known by its hairy, pointed, ten-angled calyxes. The leaves are doubly pinnate with the end-lobes confluent; they are generally hairy, the stalks red, and the whole plant has a strong hircine smell. Shining Cranefbill<sup>b</sup> has the calyxes pyramidal, angled, elevated, and wrinkled; the leaves rounded and sive-lobed: the whole plant is smooth and shining: the stalks are red.

The common Dove's-foot or foft Cranef-bill' has the peduncles and floral leaves alternate; the petals bifid, or rather obcordate; the calyxes awnless, but ending in a short point; and the stem rather erect. The stipules are also bifid: the leaves are very soft, kidney-shaped, divided half-way into sive or seven parts, and each of these lobes trifid and blunt. This is very common, especially in sandy soils. Another

very like it in many respects, but more partially distributed, has entire petals, scarcely longer than the calyx; and the stem more prostrate. Long-stalked Cranesbill has peduncles longer than the leaves, which are divided into five multissid lobes acute at the end; the calyxes are awned, and the arils are smooth. The peduncle is very long, and the lobes of the leaves are doubly triss. Jagged Cranesbill has the leaves divided into five parts, and each of those into three acute segments; the petals are of the length of the calyx, and notched, and the arils are villous; this has the leaves more and finer cut than any of the others.

Of the last section, with one-slowered peduncles, we have a handsome fort wild, but not common, with orbicular leaves, divided into five or seven parts, and each of those into three: the flowers stand on long hairy peduncles, the corollas are large, and of a deep purples. Many more species are known to the curious is, but I have only selected such as the fields, the garden, and

your little conservatory, are most likely to afford.

I have mentioned that Linnæus has fubdivided this unwieldy genus from the number of effective stamens. A celebrated modern author has, from this circumstance, made three distinct genera out of this one. 1. Erodium, containing the Myrrhina of Linnæus, or the Geraniums with five perfect stamens only. 2. Pelargonium, comprehending the Africana of Linnæus, or fuch as have feven perfect stamens. 2. Geranium, taking in the remaining species, which answer exactly to the character of the order in having all the ten stamens with anthers, and which Linnæus had called Batrachia. Rivinus long fince separated this natural genus into two, from the regularity or irregularity of the corolla. I shall not dispute whether all this be right or not. It is my defign to explain the system of the illustrious Swede as he left it.

Brownea

In this class we find a fingular plant, which has naturally eleven stamens; a number which you do not find among the classes. Having the Monadelphic character, it here forms the order *Endecandria*, and stands alone. Being a plant little known, I insist no longer on it.

The last order *Polyandria* is much the most considerable in number of genera and species. You have here Silk-Cottonk, the

Brownea coccinea Lin. Jacqu. ic. \* Bombax Lin. True

True Cotton, so much used in our manufactures, the numerous genus of Sida or Indian Mallow, Althaa or Marsh Mallow, Alcea or Hollyhock, Mallow, Lavatera, Hibiscus, &c. The two first, with Sida and Hibifcus, have one piftil only; the rest have many. Sida and Bombax have a fingle calvx, but all the others have it double. The exterior calyx in Cotton and Lavatera is trifid: in Mallow confifts of three leaflets: in Alcea is fexfid; in Hibifcus octofid; in Althæa novemfid. Lavatera, Mallow, Alcea, and Althæa, agree in having many feeds in a ring round a column, each covered with its proper aril. The feed-vessel of Hibitcus is a capfule composed of united cells including many feeds.

The officinal m species of Marsh-Mallow Althma. is known by its simple downy leaves, hoary to the sight, and very soft to the touch; they are angular, but not divided to the bottom, and therefore simple. The slowers are like those of the Mallow, but smaller and

paler.

Of Mallow there are many species: that Malva. which is so very common has an erect herbaceous stem; five or seven-lobed acute leaves, with both petioles and peduncles

Z 3 hairy.

Milors.

hairy. Davarf Mallow has a proftrate stem: orbicular leaves hollowed next the petiole, obscurely five-lobed; the fruit bearing peduncles declining. This is every way a fmaller plant. Vervain Mallow has an erect stem, rough with spreading hairs in bunches, many-parted roughish leaves, the lobes of which are obtuse and indented: the flowers large, and light purple. Another wild species called Musk Mallow , is very like this, but has the radical leaves kidney-form and gashed; the stem-leaves fiveparted, and the divisions finely cut into narrow fegments: the flowers have a musky smell, and the stem has single erect hairs fitting on a prominent point. Cape Mallow has an arborescent stem ten or twelve feet high, and the leaves five-lobed and hollowed at the bate. The whole plant is hairy, and these hairs exude a viscid aromatic juice. The flowers are deep red, and imalier than those of the common Mallow. The trivial name informs us of its country, and contequently that it stands in need of protection from you.

The gigantic, the gaudy Hollyhock is of the genus Alea: there are many varieties

PM Mes recordifolia Lin. Curtis, Lond. III. 43. Fl. Dan. 721. Ger. 930. 2. Park. 299. 1.

iata Lin. Curtis, Loud. IV. 50. Mer.

Marte es produ 20%. Dill. elth. t. 169. f. 206.

with double flowers, and different colours, as white, red of all hues from pale carnation to almost black, and yellows of different shades; but there are only two species, the first having roundish leaves, cut at the extremity only into angles; the second palmate, cut deeply into fix or seven segments, like the sig-leas. Of the first there is a dwarf variety with variegated flowers, much esteemed, and called Chinese Hollybock.

The shrub vulgarly named Althaa Fru- Hibiscus tex is an Hibifcus: a very numerous genus, comprehending no less than thirty-fix species, most of them inhabitants of either India, and not generally known here. The Althaa Frutext however is a native of Syria, and bears the rigour of our climate. though it be very late ere it produce its flowers. The specific characters are, an arboreous or woody stem, and wedge-shaped leaves divided at top into three lobes, and standing on short petioles. The flowers are bell-shaped, and of various colourspale or bright purple with dark bottoms, white with purple bottoms, variegated with dark bottoms, and yellow with the fame: these flowers being large, gay, and numerous, make a handlome appearance, and give the completest idea of the classical character.

China Rose, also, notwithstanding its name,

<sup>·</sup> Alcea rosea Mill. Illustr .- & ficifolia Lin.

Hibiscus Syriacus Lin. Curt. Magaz. 83.

is no Rose, but an Hibiscus", with a woody stem, and ovate, sharp-pointed leaves, ferrate about the edges; the colour, fize, and appearance of the flowers, when they are double, gave occasion to the name of Rose: they frequently appear on Chinese paintings and paper, and are certainly very ornamental. The Musk Plant' of the West Indies is another species of Hibiscus; its kidneyshaped seeds have a very strong smell of musk. The bark of some species " is formed of fibres strong enough for cordage. One of them is cultivated in the West Indies for its pods, which they put into their foups x. But all this we have nothing to do with as botanists.

## LETTER XXV.

THE CLASSES DIADELPHIA AND POLYADELPHIA.

June the 4th, 1776.

FTER a short excursion, we are returned, dear cousin, among your old acquaintance; and you have only to apply to the term Diadelphia, which is the name of the seventeenth class in Linnæus's system, all the knowledge you first acquired from the letter on Papilionaceous flowers, and which you have fince increased so much by your observation and experience. You have admired the fingularly admirable and beautiful structure of these flowers, in which all the plants of this class agree: you will now not be displeased to accompany me in an enquiry into their generic and specific differences. The number of genera in this class is 57, of species 695. The orders are four, taken from the number of stamens, which in the first order is five, in the second six, in the third eight, and in the fourth ten. In the order Pentandria however there is only one genus; in the order Hexandria two; and in the order Octandria three; fo that you perceive the last

(Decandria) absorbs the far greater part of the class; and what you have learnt of papilionaceous flowers belongs indeed principally to this order. Of the three first orders, there are only two genera which you will have an opportunity of observing; and we

will begin if you please with them.

Fumitory has two filaments, each of them terminated by three anthers; it has the clasfical character therefore, and must be of the order Hexandria. This genus has, besides this, a two-leaved calyx, a ringent rather than a papilionaceous corolla, the upper lip however answering to the banner, the lower lip to the keel, and the bifid chaps to the wings: the base of each lip is prominent, but the upper one the most; and one filament is inclosed in each. Common Fumitory 2, which you will readily meet with as a weed in your kitchen garden, is known by a weak, diffuse branching stem, multifid leaves dividing into three, and the lobes trifid: the flowers growing in a raceme, and each being fucceeded by a round or rather obcordate one-feeded pericarp.

Polygala. Milkwort has eight filaments, each terminated with an auther, and all united at bottom; it appertains therefore to the order Octandria of this class. The characters

Fumaria officinalis Lin. Curtis, Lond. II. 52. Ger. 1088. 1. Park. 287. 1. Fl. Ruft. t. 68. Engl. Bot. 589. F. claviculata, Engl. Bot. t. 103. F. cava, Curt. Magaz. 232. F. folida, 231. F. lutea. Engl. Bot. t. 588. F. parviflora, 590.

of the genus are, a five-leaved calyx, with two of the leaflets like the wings of the papilionaceous flower, and coloured: the banner of the corolla is cylindric; the legume is obcordate, or inverse-hearted, and twocelled. Many of the species have a beard. crest, or pencil-formed appendage to the keel; those which have none are called beardless: and hence a commodious subdivision of this large genus; the last are subdivided into shrubby and herbaceous; the herbaceous again into fimple and branched. Of thirty-eight species we have only one wild, and that is common on dry pastures and heaths2: it is of the crested division. and bears the flowers in a raceme; the stem is herbaceous, simple, and procumbent, and the leaves are linear. This is a lowly plant, with pretty flowers, blue, red, or white. There is a beautiful species b in the green-house, from the Cape, with a shrubby ftem; oblong, smooth leaves, blunt at the end; and handsome flowers, large, white on the outfide, but bright purple within; the keel crested, and shaped like a half moon. Senega° root, fo famous among the American Indians as an antidote to the bite of the rattle-snake, is from a species of this genus. The plants of the order we are now to

The plants of the order we are now to

<sup>\*</sup> Polygala vulgaris Lin. Fl. Dan. 516. Ger. 564. 5. Park. 1342. 2. Engl. Bot. t. 76.

Polygala inyrti cha Lin. Mill. Illustr. Polygala Senega Lin. Mill, Dict.

examine are obvious, not only by their papilionaceous flowers, but by their compound leaves, which in the greater part are pinnate, winged, or feathered, but in others trifoliated. In some genera the pinnate leaves have the leaflets in pairs only, but it is more common to have them terminate in an odd onef. Many of this pulse tribe have stems too weak to sustain themselves: they fly therefore to some stronger plant or other prop for support, and they are furnished with the necessary means of helping themselves, either by twining their stalks about and embracing their friends, or else by throwing out flender threads, like the vine, called claspers or tendrils, by which they lay fast holdh.

Most of these plants having fruits that are esculent either to us, to quadrupeds or to birds, produce flowers in great abundance, and close bunches; in some of the genera they grow in a kind of umbeli, much like

d As in Trifolium or Trefoil, which has its name from this circumstance, Lotus, Medicago, Erythrina, Genista or Broom, Cytisus, Ononis, Trigonella, Phafeolus or Kidney-Bean, Dolichos and Clitoria.

o Orobus, Pifum or Pea, Lathyrus or Everlasting

<sup>8</sup> Phaseolus, Dolichos, Clitoria, Glycine. <sup>h</sup> Pisum, Lathyrus, Vicia, Ervum.

Lotus, Coronilla, Ornithopus, Hippocrepis, Scorpiurus.

those of the second order of the fifth class. I mention these circumstances, not as clasfical characters, but as leading features that may give you a shrewd suspicion, rather than a certain assurance. When you find a plant endued with some of those subordinate characters, you, I am certain, will not determine it at once upon them: no. they will only lead you to a more strict examination. Neither pinnate or trifoliate leaves, weak twining or climbing stems, nor even papilionaceous flowers, will fatisfy your discerning eye, till you have seen the union of the filaments at bottom. If you can procure any species of Sophorak, you will be convinced of this; for without fuch caution you would infallibly have been mifled; this genus agreeing with the pulse tribe in every respect, except in having the ten filaments distinct.

The proper character of this class, you know, is to have the filaments in two distinct bodies and the character of the order Decandria is to have nine filaments united at bottom into a membrane surrounding the germ, and the tenth single, filling up the opening which is lest for the germ to disengage itself, when it has arrived at a state proper to pass into a pod or legume. I must advertise you however that this is not strictly

<sup>\*</sup> A genus of the class Decandria and the order Mozogynia. Angyris, Cercis, &c. have also the same appearance.

true of all the genera; there are no fewer than eighteen out of fifty, which have all the ten filaments connected; so that the germ cannot grow into a legume without tearing afunder the membrane formed of the filaments. You must not therefore be deterred from fetting down a plant as of the Pulse tribe, and of the class Diadelphia, when you find the ten filaments united into one, inclosed within a papilionaceous flower, and furnished with the other marks of the class. Of those which answer regularly to the classical character, some have a pubefcent stigma1, and the rest are distinguished by their legumes, as we shall now see; for we are going to examine their distinctive marks more narrowly.

Spartium You will observe in this class some trees, and many fhrubs, with papilionaceous flowers, as Common<sup>m</sup> and Spani/b<sup>n</sup> Broom; both of a genus in which the ten filaments are all united, and form a membrane adhering close to the germ: the stigma grows along the upper fide of the top of the style, and is villous; the calyx is continued downwards, and is marked beneath with five little notches at the tip. Spanish Broom, with some other species, has simple leaves; in

> <sup>1</sup> Colutea, Phaseolus, Dolichos, Orobus, Pisum, Lathyrus, Vicia.

m Spartium scoparium Lin. Curt. Lond. V. 52. Fl. Dan. 313. Blackw. 244. Ger. 1311. 1. Park. 229. 1. <sup>n</sup> Spartium junceum Lin. Curt. Magaz. 85.

the rest they are ternate, tresoil, or threeleaved. In Common Broom however there is a mixture of both. In the first also the leaves are lance-shaped, and the rush-like branches are opposite, round, and produce the flowers from the top, in a loofe spike. In the fecond the branches are angular, and the flowers come out fingly for a confiderable length towards the top. They are large, and of a bright yellow in both species. There is also a Spanish Broom with a white flower o; which has leaves like the other, but the branches striated, and the flowers in fhort spikes or clusters on the fides of them; they are succeeded by large oval pods containing one feed, whence the trivial name, Portugal Brooms with trifoliate leaves, and yellow flowers, differing little from ours: and a fort with prickly branches, thence called Prickly Cytifus.

We have some wild shrubs of an hum-Genista. bler growth, somewhat resembling these, but of another genus called Genista; the characters of which are—a two-lipped calyx, the upper lip two-toothed, the lower three-toothed; the banner of the corolla oblong and turning downwards from the pistils and stamens; the pistil depressing the keel, and the stigma involute. Dyer's weed, called also Wood-waxen and Base Broom, which

Spartium monospermum Lin.

Spartium, spinosum Lin.
 Genistra tinctoria Lin, Fl. Dan. 526. Ger. 1316. 1.
 Park. 229. 7. Engl. Bot. t. 44.

grows in pastures and headlands, has

smooth lance-shaped leaves, and erect. round streaked branches. Needle Furze of Petty Whin', which you will find wild on heaths, has fmall lance-shaped leaves, slender branches armed with long, fimple fpines; the flower branches are short, havno spines, and have five or fix flowers in a cluster at the end of them: the colour of the corolla in both species is yellow: and you would at first suppose that the former was a Spartium, and the latter a Furze, or of the genus Ulex; which however differs from both in having a two-leaved calyx, with the legume fo fhort as scarcely to emerge from it. We have only one species, than which nothing, as you know, is more common on all our heaths; it has the three different names of Furze, Gorse, and Whins in different parts of the kingdom.

Ulex.

Ononis. Restharrows are lowly shrubs, or rather undershrubs, with purple flowers, growing on commons, barren pastures, and headlands of corn-fields; they have the name from the strength and matting of the roots, which circumstance has induced the Dutch to fow them on their fea-banks. The cylinder of filaments is quite entire at bottom, without any fiffure, in this genus;

Ulex europæus Lin. Fl. Dan. 608. Ger. 1319. 1. Park. 1004. 1.

<sup>&</sup>lt;sup>1</sup> Genista anglica Lin. Fl. Dan. 619. Ger. 1320. 4. Park. 1004. 4. Engl. Bot. t. 132.

the calyx is parted into five linear divisions; the banner of the corolla is striated; and the legume, a fection of which is a rhomb, is turgid and fessile. We have two sorts, one' with prickly smooth branches, and the flowers in a raceme, but coming out fingly: the other " with villous leaves and branches, but without spines; the flowers in a raceme, but generally two together; both have ternate leaves, except that towards the top

they are fimple.

In Anthyllis the calyx is turgid and in- Anthylcludes the legume, which is fmall and lis. roundish, containing one, or at most two feeds. The only species we have wild is herbaceous, is called Ladies Finger or Kidney-Vetch, and is not uncommon in chalky pastures; it has unequally pinnate leaves, and a double head of yellow flowers, but this latter character is not constant. The leaves are pubescent, and confist of three or four pairs of leaflets; except two under the umbel, which are digitate. There are feveral flowering shrubs of this genus; as that which is generally called Jupiter's Beard or Silver Bulby, from the splendid whiteness of the leaves, which is owing to a fine nap

or down that covers them: they are equally pinnate: the flowers are produced at the extremity of the branches in small heads,

and are yellow.

Lupinus. Lupins, which are so well known in the flower-garden, agree in a two-lipped calyx, in having five of the anthers round. and five oblong, and in the shell of the legume being coriaceous or leathery. The common Whitex fort, which is cultivated as a pulse in most of the southern parts of Europe, has the flowers growing alternate, without appendages; the upper lip of the white corolla is entire, the lower threetoothed: the feeds are orbicular and flatted. There are three forts with blue flowers: the Perennialy, which is the only one that is not annual, with alternate, unappendaged flowers; the upper lip of the corolla notched, the lower one entire. This is an American plant; the digitate leaves are composed of ten or eleven leastlets, whereas those of the former have no more than seven or eight: the flowers grow in long loofe spikes, and are pale blue. The Great Blue2, with alternate appendaged flowers; the upper-lip two-parted, the lower threetoothed. This has a strong stem, covered with a foft brownish down; the leaves have nine, ten, or eleven hairy, spatulate leaf-

<sup>\*</sup> Lupinus albus Lin. Riv. tetr. Blackw. 282.

<sup>&</sup>lt;sup>2</sup> Lupinus hirsutus Lin.

lets: the flowers are in whorls, forming a fort of spike; they are large, and of a beautiful blue: the pods are very large, and have three roundish compressed seeds, very rough and of a purplish brown. Narrow-leaved or tall blue Lupin2 has the flowers alternate and appendaged or pedunculate; the upper lip of the corolla twoparted, the lower three-toothed: the lobes of the leaves are linear. The Varied is not very different in appearance from this: the flowers grow in half whorls, and are appendaged; the upper lip is bifid, and the lower flightly three-toothed: the corollas are light blue or purple. It is shorter than the last; the leaves have fewer leastlets, and stand on shorter petioles. The Hairy c has the flowers in whorls and appendaged, with the upper lip two-parted, like the Great Blue Lupin, which it much refembles in stature and appearance; but the corollas are flesh-coloured, with the middle of the banner red; the lower lip is entire; the plant is hairy all over, and the leaves are lance-shaped and a little obtuse at the end. The Yellow is esteemed for the sweetness of its flowers: they grow in whoris and on peduncles: the upper lip of the corolla is two parted, the lower three-toothed. Thus

Phaseo-

have you a history of the whole genus of Lupin, for these are all the species hitherto known: and as you may easily have them growing together, you may compare them at leisure, and ascertain all their agreements and differences. Could we do this in every genus, how clearly might we distinguish the species! But remember that culture may produce sistitious characters, which mislead

unwary Botanists.

In all the genera hitherto examined, the filaments have made one body at bottom; in the rest, which I shall now offer to your consideration, nine only are united, and the tenth is free, according to the proper character of the class. We will begin with some genera, distinguished (as I mentioned before) by a pubescent stigma. Phaseolus or Kidney-Bean, in having the keel with the stamens and style spirally twisted, possesses one obvious character, that discriminates it sufficiently from all the other genera. Some of the species have an outer calyx, consisting of two roundish leasters, which may more properly be called bractes. La-

Lathyrus may more properly be called bractes. Lathyrus or Everlasting Pea has a flat style, villous above, growing broader upwards: in this it differs from the Pea, which has a triangular style keeled above: both genera have the two upper divisions of the calyx shorter than the other three, and, in other respects, are very nearly allied. Some species of Lathyrus have one flower only on a peduncle;

peduncle: of these we have two wild ones; one with yellow flowers, supporting itself among the corn by leafless tendrils, and having broad stipules shaped like the head of an arrow: the other with crimfon flowers, long narrow leaves difficult to be diftinguished from the grass among which it grows, and fmall, fubulate, or awled ftipules. The first is called Yellow Vetching: the second, Crimson Grass Vetchs. Sweetscented Peas, with some few others, has two flowers on every peduncle; each tendril has a pair of oblong ovate leaves, and the legumes are rough. The banner of the corolla is dark purple, the keel and wings light blue: but there are varieties; one all white, and another with a pink banner, wings of a pale blush, and a white keel; this is called Painted Lady Pea. Tangier Peah, another of the biflorous section, has the two leaves alternate, lance-shaped and smooth; the stipules shaped like a cresent. The flowers grow on short peduncles; have a purple banner, with wings and keel of a bright red, and are succeeded by long

Lathyrus Aphaca Lin. Mill. fig. pl. 43. Curtis, Lond. V. 51. Ger. 1250. Park. 1067.

g Lathyrus odoratus Lin. Curtis's Magaz. 60.

h Lathyrus tingitanus Lin. Jacq. hort. 1. 46. Curt.
Magaz. 100.

iointed pods. Everlasting Peai is of the last division, having many flowers produced on one peduncle: this has also conjugate leaves, that is, growing in pairs, furnished with a tendril or clasper; the form of the leaves is elliptic or oval; and the stems, which climb very high, have membranaceous wings on each fide between the joints: the flowers are red. There is a variety of this in the gardens, with broader leaves, larger and deeper-coloured flowers. There is another fort not very different from thisk, having fword-shaped leaves; and a third1. growing in woods, bogs, and wet meadows, which has many-leaved tendrils, and lance-shaped stipules: the leastets are six; and there are from three to fix flowers on each peduncle; the corolla is blue, with the greatest part of the wings and keel white. One species of this section m, with vellow flowers, two-leaved tendrils, which are extremely simple, and lance-shaped leaves, is very common in pastures, hedges, and woods:

Vicia.

Vetch or Tare is sufficiently distinguished by having a stigma transversely bearded on

the under fide. The species, which are eighteen in number, may be ranged under two divisions, the first comprehending such as have flowers in bunches on peduncles; the fecond, those which are axillary, or have the flowers fitting almost close to the stem and coming out from the angle which the leaves form with it. Of the first divifion we have the Tuftedn and Wood Vetcho wild: both having flowers in bunches many together, but in the first imbricate; in this also the leastets or component leaves are lance-shaped and pubescent, and the Ripules entire: in the second, the leastets are oval, and the stipules slightly toothed. The cultivated, and feveral wild forts, are of the fecond division. The first has erect, fessile legumes, mostly two together: the leaves are retuse, and the stipules spotted. Of the others, Spring Vetch 4, which is very nearly related to the former, has however the legumes generally fingle; the lower leaflets retuse, the upper ones narrow, and almost linear: the leaflets are from four to ten; and the stipules are spotted, as in the former. Bulh Vetch\*

<sup>&</sup>lt;sup>q</sup> Vicia lathyroides Lin. Engl. Bot. t. 30. <sup>e</sup> Vicia dumetorum Lin. Riv. tetr. 501

has about four erect legumes growing together on short pedicles: the leaslets are ovate, and quite entire; they decrease in fize towards the end of the leaf; it ramps in hedges. The Bean' is placed by Linnæus in the Vetch genus; and very justly, fince it agrees with them in the characters of the fructification, and differs only in having a stouter stalk than supports itself, and therefore is not furnished with tendrils. Its native place of growth is supposed to be not far from the Calpian Sea, on the borders of Persia. All the different forts of Bean are in reality but varieties from the same original flock: you understand me to speak of Beans properly so called, in exclusion of Kidney Beans and others, which are not merely specifically different, but also of another genus.

Colutea.

Of the same section with pubescent stigmas, is a genus of well-known shrubs called Colutea: distinguished by their quinquesid calyx; and instated legume, opening from the base by the upper suture: the English name of Bladder-Sena is taken from the latter character. Common Bladder-Sena has an arboreous stem, and inversely-hearted leaves. It grows twelve or sourteen feet high; its winged leaves have sour or sive pairs of grayish leastlets; the slowers

<sup>5</sup> Vicia Faba Lin.

t Colutea arborescens Lin. Curt. Magaz. 81.

come out from the axils, two or three together, on slender peduncles; they are yellow with a dark-coloured mark on the banner. This grows wild in the fouthern countries of Europe. There is another, which comes from the East, and has flowers like this, only of a brighter yellow; differing in being a much lower shrub, and in having nine pairs of small, oval, entire leaflets to each leaf. A third, about the fame height with the fecond, but with branches still more slender, comes from the fame country: the leaves of this have five or fix pairs of small heart-shaped leaflets; the flowers are smaller, and of a dark red. marked with yellow. It is a doubt whether these be specifically different from the first ": there is however one from the Cape of Good Hope, with scarlet flowers, which is very distinct : for it is a low, weak shrub. with leaves composed of ten or twelve pairs of oblong-ovate, hoary leaflets; the flowers are long, owing to the length of the keel. for the banner is shorter than that, and the wings are minute. You will eafily fuppole, from its country, that it cannot stand the cold of a severe winter with us: it does not shrink however from a mild one. in a dry soil and warm situation. There is also an herbaceous species, with smooth

<sup>&</sup>quot;Figured in Comm. rar. t. 11. and Mill. fig. 100.

Colutea frutescens Lin. Mill. fig. pl. 99. Curt.

Magaz. 181.

W Colutea herbacea Lin. Comm. hort. 2. t. 44.

linear leaflets; but this is an annual plant of little beauty, and therefore rarely cultivated

Cytifus. There are feveral other shrubs of the Pea-bloom tribe: as the different species of Cytifus, of which Laburnum\* is one. This is known by yellow flowers hanging in large fimple racemes, and three oblongovate leaflets to each leaf. There is a variety with narrower leaves and longer bunches of flowers, more common in shrubberies than the first, which is a larger tree, and comes to excellent timber; but this, making a better appearance when in flower, is preferred in ornamental plantations. Sefste-leaved Cytisus, vulgarly called Cytisus secundus Clusii, has the flowers in short erect racemes, at the ends of the branches: each flower has a little triple bracke at the base of the calyx; the leaves on the flowering branches are fessile, but the other's are petiolate. The flowers are of a bright vellow, and the pods are short, broad, and black. Evergreen Cytifus has the flowers coming out fingly from the fide of the stalk, with very hairy, trifid, obtufe, oblong, fwelling calyxes: the stalks extremely hairy; the leaves also hairy, especially underneath. The flowers are pale yellow; and the pods long, narrow, and rough.

<sup>\*</sup> Cytisus Laburnum Lin. Jacq. Austr. 4. t. 306. Curt. Magaz. 176.

y Cytifus festilifolius Lin. Duham. Arb. 1. Curt. Mag. t. 255. Cytisus hirfutus Lin. Jacq. obs. 4. 96.

All these, and the rest of the species, agree in a two-lipped calyx, the upper lip bisid, the lower three-toothed; and a legume attenuated at the base; and pedicled, with several seeds in it. The leaves are ternate.

Robinia has a quadrifid calyx; an ex-Robinia. panding, reflex, roundish banner; and a gibbous, elongate legume, containing feveral feeds. The tree which you admire for its long racemes of fweet-fmelling white flowers, hanging down like those of Laburnum, is of this genus: I mean the Baftard Acacia a called in North America, its native country, Locust-tree. The leaves are pinnate, confisting of eight or ten pairs of oval leaflets terminated by an odd one; all entire, and fitting close to the mid-rib: the stipules are armed with strong crooked thorns; and the flowers come out fingly, or only one on a pedicle in the racemes. The Caraganab, a Siberian shrub, has leaves abruptly pinnate, that is, winged, not terminated by an odd leaflet; they have four or five pairs of oval leaflets: this has no spines, and the yellow flowers come out fingly from the axils. There are feveral other trees and shrubs of this genus; but these are the most known.

Coronilla

Robinia Pfeudacacia Lin. Seba Muf. 1. t. 15. f. 1. Duham. Arb. 2. t. 42.

b Robinia Caragana Lin. Duham. Arb. 3. The beautiful R. hispida is figured in Curt. Magaz. 311.

Coronilla Coronilla is another genus of shrubs, comprehending however some herbaceous plants. They all agree in a two-lipped calyx; the upper lip having two, the lower three little teeth; the superior teeth conjoined; in a banner scarcely longer than the wings; and in a very long, straight legume, contracted between the feeds, and, instead of opening by the futures, falling off in joints .- Scorpion Senac is a species of this genus very common among shrubs: it is immediately known, by having the claws of its yellow corollas three times as long as the calyx; two or three flowers come out together upon long peduncles from the fides of the branches, which are flender, and angular: the leaves are pinnate, and composed of three pairs of leaflets terminated by an odd one: the legumes are long, slender, taper, and pendulous; the feeds cylindric. There are feveral beautiful shrubs of this genus, but too tender to bear the open air in our climate.

Indigotera.

The plants from which Indigo is made 4 are of this class; and many of the kindred genera refemble them in quality as well as outward form and character. Scorpion Sena in particular, it is faid, will yield a dye nearly equal to Indigo, if the leaves are fermented in a vat in the same manner as is

Indigofera Lin, Mill. fig. 34.

practifed

c Coronilla Emerus Lin. Mill. fig. 132. Curt. Mag.

practifed with those plants; and you remember complaining perhaps, that the yellow flowers of the Lotus would turn blue in drying, unless you took care to keep them separate from other plants, and to

change them often.

Liquorice is also of the same class: it Glycyrhas a two-lipped calyx, with the upper lip rhiza. divided into three parts, and the lower abfolutely fimple and undivided; the legume is ovate and compressed, with very few kidney-shaped seeds. The species which is cultivated for the fake of its roots has fmooth legumes, no stipules, and pinnate leaves confisting of four or five pairs of leaflets, terminated by an odd one, which is petiolate. It is a lofty plant for an her-baceous one, the stalks being from four to five feet high; the flowers come out in erect spikes from the axils, and are pale blue.

Hedysarum is a most numerous genus, Hedysacontaining no fewer than fixty-feven spe-rum. cies, all however conspiring in having the keel transversely obtuse, and the legume jointed with one feed in each joint. The genus is subdivided into four sections, from the leaves; which in the first are simple: in the fecond, conjugate; in the third, ternate; and in the fourth, pinnate. I shall prefent you only two species, and they of

e Glycyrrhiza glabra Lin.

the last section. One transplanted from Italy into the gardens; and the other from a wild state to a cultivated one. The first is the French Honey sucklef, which is distinguished from the rest by a diffused stalk, and by its jointed, prickly, naked, straight legumes; its pinnate leaves point it out to be of the fourth section: they have five or fix pairs of leaflets, terminated by an odd one; and from their base comes out a long peduncle, fustaining spikes of beautiful red flowers. The other is the Saintfoin's; the characters of which are-an elongated stem, the wings of the corolla equalling the calyx, and one-feeded prickly legumes: this has also, of course, pinnate leaves. It adorns the chalky hills with its beautiful spikes of red flowers; and contributes largely among many others of this class to feeding of cattle. For this the Trefoils are most justly celebrated; there are forty-fix species of them, all having the flowers growing in a head; and the legume very short, scarcely emerging from the calyx, not opening, but falling off entire, and containing but one, or at most two feeds. Though this be a genus eafily distinguished by its habit, yet the characters are by no means constant, and perhaps there is not one com-

Trifo-lium.

Hedyfarum coronarium Lin. Fl. Rust. 115.

Ger. 1243. 1. Park. 1082. 1. Fl. Ruft. t. 47. Engl. Bot. t. 96.

mon to all the species. White Trefoil, commonly called Dutch Clover, has a creeping, perennial stem; the heads umbelled; and the legumes covered and four-seeded. Purple Trefoil, Honeysuckle Trefoil, or Red Clover, has the flowers growing in globular subvillous spikes, girt with opposite membranous stipules; and the corollas all of one petal. There are many wild species of this genus; but the Yellow Trefoil, cultivated under this name, or that of Nonsuch, is of another genus, as we shall see presently.

Lotus has a tubular calyx: the wings of Lotus. the corolla clapping close together upwards longitudinally; and an upright cylindric legume. The wild species is called common Bird's-foot's, and is distinguished by its decumbent stems, many flowers growing together in depressed heads and exactly cylindric, spreading legumes. The corollas

are of a bright yellow.

Lucerne<sup>1</sup> is of the genus Medicago, the Medicacharacter of which is, that the keel of the gocorolla bends down from the banner, and that the legume is flatted and spiral, or

Trifolium repens Lin. Curt. Lond. III. 45. Ger. 1185. 1. Fl. Rust. t. 34.

wreathed

wreathed like the shell of a snail. The specific character is this, the stem is erect and fmooth, the flowers grow in a raceme, and the legumes are contorted: the colour of the corollas is blue. The species cultivated under the name of Trefoil or Nonfuch " has the stems procumbent; the flowers in oval spikes; and the legumes kidney-form, with one feed only in each; the corollas are small and yellow. In a cultivated state the stems draw each other up, and lose, in a great measure, their natural procumbency, as does also Bird's-foot Trefoil, when it has other plants about it, as in grass-fields, &c. There is a species of Medicago called polymorphous or many-form, from the variety of appearances it puts on, or from the change of figure in the pod. We have one variety very common wild, called Heart-Clover from the form of the leaves, which are also generally spotted: each head confifts of four or five little yellow flowers; the legumes are globose, spiral, and covered with very diverging spines: and in the garden you have the vegetable Snails P, with large, spiral, globose legumes, naked, or not covered with spines; and the Hedge-

hogs, whose legumes are closely armed with long spines pointing every way. These all have the stem diffuse; the stipules toothed, and the legumes spiral. This class has also its vegetable Caterpillars, but they are

of another genus r.

I fear you will think I have already made this letter too long. However, as it may be some time before you hear from me again; as the next class is a very small one, and completes the set of plants with united filaments, I will trespass on your patience whilst I go through it.

#### THE CLASS POLYADELPHIA.

The Class Polyadelphia, then, comprehends all such flowers as have the filaments united at bottom into more than two parcels. The filaments are in bunches, or pencilled as one might call it, fince they are collected into bodies resembling a camel's-hair pencil. If you were not to attend to this character, you might easily suppose these plants to belong to the class Polyandria; for they have no striking appearance, like the pulse tribe and some others, announcing them immediately to range under this class.

<sup>r</sup> Scorpiurus. Rev. tetr. 210.

<sup>4</sup> Med. polym. intertexta. Mor. f. 7, 8, 9.

There are four orders, taken from the stamens: Chocolate's is in the first, Pentandria, a genus called Monsonia in the second: Citron, comprehending Oranges and Lemons, in the third; and eight genera in the fourth. The whole number of species is only sixty-five.

only fixty-five.

The beautiful, odoriferous, well known, and defervedly efteemed genus of Citrus has these characters—a small calyx five-toothed at top; a corolla of five oblong petals; about twenty stamens, placed cylindrically round the germ, with the silaments connected rather slightly, sometimes into more, sometimes into sewer parcels: one pistil, and, for a fruit, a berry generally nine-celled, with a bladdery pulp, in which the seeds are lodged.

You will have pleasure in examining at leisure the elegant species of this genus, and in regaling your senses whilst your mind imbibes instruction. When they are in fruit, you distinguish them immediately; but when they are not, you will find that the Citron' and Lemon have the petioles linear or all of a size, like most other petioles; whereas the Orange and Shaddock have the petioles winged in shape of a

<sup>t</sup> Citrus Medica Lin. Virg. georg. edit. Mart.

heart:

Theobroma Cacao Lin. Sloan. jam. 2. t. 160. Merian. furin. t. 26 & 63. Catefb. car. App. t. 6.

heart; fo that the main leaf feems to grow out of a smaller one.

The Orange " and Lemon may be distinguished by pointed leaves from the Shaddock which has them obtuse, and emarginate or notched at the end: not to mention the great fize of the fruit, the flowers of this grow more in racemes, which are also a little nappy or woolly. I dare prefume that you are by this time fo great an adept in Botany as readily to admit, in spite of the information of your taste to the contrary, that the Seville and China Oranges may be varieties of the same species, owing all their difference to climate. Neither perhaps do you find much difficulty in perfuading vourself, that the large and generous Lemon may not be specifically different from the little, round, four Lime; not with standing some little difference in the leaves and the spines on the branches of the latter. The position of the stamens informs you that this genus is of the order Icosandria.

The genus Hypericum, in the last order Hyperi-(Polyandria) of this class, has many more cum. species than all the other genera put together. Several of them are wild, and feveral others are commonly cultivated among shrubs: they are not however all shrubs.

for many species are herbaceous. All plants

Citrus Aurantium Lin. Mill. Illustr.
v Citrus decumana Lin. Rumph. amb. 2. t. 24: f. 2. B b 2 do

do not exhibit the classical mark, in this or any other class, with equal evidence; in this genus the numerous stamens will cafily separate from the receptacle in pencils or parcels, and thus evidently show what is their proper place in the fystem. Being thus certified that your plant does not belong to the class Polyandria, but to this, you will eafily diffinguish it from its congeners, by its five-parted calyx including the germ; by its corolla of five-petals; by the abundance of stamens, usually forming five squadrons; and by the feed-vessel being a capfule, divided into as many cells as there are styles to the flower; these are either one, two, three, or five in number; and hence a subordinate division of the genus into four fections: there is however only one species with one style, and there are only two species with two; the far greater number have three: and among these are all the European ones.

Common Saint John's wort whas two characters fo remarkable that it cannot well be mistaken, as soon as they are understood: for it has an ancipital or two-edged stem, that is, roundish, or a little flatted, and running out longitudinally into two little edges or membranes opposite to each other: and its obtuse leaves are punctured all over their

W Hypericum perforatum Lin. Curtis, Lond. I. 57. Mill, Illustr. Ger. 539. 1. Park. 573. 1. Engl. Bot. 295.

furface, fo as to appear, when held up against the light, as if they had been pricked with a pin. Another wild fort not near fo common, growing in moist hedges and woods, and called Saint Peter's wort has square stalks; it is about the same size with the other, but does not branch fo much: the leaves are shorter and broader. and have none of the pellucid dots which are so remarkable in the former. Trailing Saint John's worty is a pretty little plant, found on dry pastures and heaths; it has two-edged, prostrate, filiform stems; smooth leaves; and axillary, folitary flowers. Upright Saint John's wort is an elegant species, growing in woods and heaths; with columnar stems; stem-clasping, smooth, heart-shaped leaves; and serrated calyxes with the teeth glandular.

The two most common forts, cultivated among other thrubs, are the flinking shrubby and Canary Saint John's worts. They have both a rank smell, resembling that of a goat, which, however, in some circumstances, and at certain distances, seems to

be fweet, at least to some persons; both also have three pistils: but the first is a much lower plant, and has the stamens longer than the corolla; whereas in the fecond they are shorter. Garden Tutsan' is 'evidently of this genus: it is one of those which have five piffils; the stems are low, fimple, herbaceous, and quadrangular; the leaves smooth, and quite entire; the roots creep extremely, and the flowers are very large. Wild Tutsan, or Tutsan Saint John's wortd, called also Park-leaves, has a shrubby two-edged stem; three pistils, and a berried fruit, or foft, coloured pericarp: the flowers of this are small, and the stamens extend beyond the corollas. It grows wild in woods, and fometimes in moist hedges. Of the more rare and tender forts, the Majorca Saint John's wort ' is very distinguishable by the warts all over the flender red branches; the leaves also are repand or waved on their edges, have fmall protuberances on their under furface, and at the bate embrace the stalk: the flowers are large, with the stamens a little shorter than the corolla, and five pistils. Lastly, Chi-

# LETTER XXVI.

#### THE CLASS SYNGENESIA.

August the 24th, 1776.

HOUGH this letter, dear cousin, will arrive late in the feafon, vet it will be in time for you to examine the far greater part of the class Syngenesia, or tribe. of compound flowers, which blow chiefly in the autumn. You are well aware that the effential character of this class is the union of the anthers. You are perfect miftress of the structure of a compound flower, and of the different florets that compose it s. And lastly, the several orders into which the class is divided are familiar to you, and the foundation of them well understoodh. Very little therefore remains to premite, before we proceed to the examination of the genera, and species. The accommission or should

This is by much the more numerous of the natural classes; and therefore it should, in all probability, be more difficult to find sufficient generic and specific distinctions here than in any other: such however

E See Letter VI.

h See Letter X.

The number of genera being 116, and of species 1247.

have been the fagacity and industry of Linnæus, that I hope you will not find any great difficulty, even in the two first orders, which contain above two-thirds of all the genera.

# THE ORDER POLYGAMIA ÆQUALIS.

To facilitate the investigation, in the first order, Polygamia Æqualis, it is subdivided into three battalions, eafily diffinguished by the most obvious characters. The first contains the flowers composed wholly of ligulate florets, which are the Semiflosculous flowers of Tournefort: the fecond contains the capitate or headed flowers: and the third the discoid flowers. So that there are no radiate flowers in this order: the flowers of the first section are wholly made up of such florets as compose the ray of these: in the two other festions there are none of these ligulate corollas or femisforets, but the compound flower is wholly made up of tubulous corollas, or florets properly fo called: in the fecond fection thete are long, and the calyx bulges out at bottom, as in the thiftles; in the third, the flowers resemble a Daify, or other radiate flower, with the ray pulled off.

The calyx, the receptacle, and the crown of the feed will in general be found sufficient

to furnish the generic distinctions in this order's a destinate of the state of the stat

Tracopo- Thus Tracopogan or Goat's beard is known by its simple calyx, naked receptacle, and feathered stipitate down: and these three circumstances are sufficient to distinguish this genus from all others; provided you have first affured yourself, by the rules already laid down, that your flower is of the compound tribe, that each floscule has the anthers united into a cylinder, which the pistil, terminated by two revolute stigmas, perforates; and that the corollas are all ligulate: for thus it is that you come at the class, order, and section. I cannot suppose that you have any difficulty in diffinguishing a natural compound flower from a double one, the creature of art and culture, though the fimilarity may mislead those who are not

<sup>\*</sup> The calyx is fingle, or fimple, in Seriola, Geropogon, And yala, Tragopegon: calycled, or furnished with a second set of leastlets at the base, in Cichoreum, Picris, Crepis, Chondrilla, Prenanthes, Lapfana, Evoferis; in the rest imbricate. The receptacle is villous in Scolymus, Cithoreum, Catananche, Seriola, Hypocharis, Geropogon; in the rest it is naked, that is has neither hairs nor chaffs between the floicules. Scoiymus and Lafana have no pappus or down: in Seriola, Andryala, Crepi, Prenanthes, Latiuca, Hieracium, Sonchus, the down is simple; in Hypochæris, Geropogon, Tragopogon, Picris, Leontodon, Scorzonera, Chondrilla, it is feathered; in Cichoreum the crown of the feed is five-toothed, in Catananche fiveawned, in Hyoferis crowned with a calyxcle. In some genera this down fits close to the feed, in others it is flipid or stipitate: that is, has a stem interpoled between it and the feed what for the the said of the field

accustomed to observation; because I am certain that if you have the least doubt, you will pull out a floscule, in order to see whether it has a feed, stamens, and pistil, or is only a mere flat petal. But to return to our plant.—Yellow or Common Goat's beard, which grows wild among the grafs in meadows, is distinguished by entire upright leaves, and by the segments of the calyx at least equalling in length the outer floscules. Towards noon you will not easily find this plant, because the flowers are then always closed: after the flower is past, Goat's-beard is very apparent, on account of the large globe formed by the down of the feeds, till the wind has at length torn them from the receptacle, and wafted them separately to distant places of

salfafy m, which your gardener will furnish you with from the kitchen garden, has the segments of the calyx much longer than the floscules, and the peduncles swell out remarkably under the flower; which is

large, and of a fine blue.

. . .

Another plant of this tribe which you may scorzonealso have from the kitchen garden, is the ra. Scorzonera, of a genus nearly allied to the last; agreeing with it in having a nakedreceptacle and a feathered stipitate down,

Tragopogon pratenfe Lin. Mor. Hist. f. 7. t. 9. f. r. Ger. 735. 2 Engl. Bot. 434.

<sup>&</sup>lt;sup>m</sup> Tragopogon portifolium Lin. Mor. t. 9. f. 5. Ger. 735. Fl. Dan. 797. Pl. 25. f. 1. Engl. Bot. 638.

but differing from it by an imbricate calyx, with the scales membranaceous about the edge. The cultivated species has a branching stem, and entire, stem-clasping leaves, slightly sawed on their edges; the flowers are of a bright yellow.

Sonchus & Lactuca.

Sowthifile and Lettuce agree in a naked receptacle, an imbricate calyx, and a simple down to the feed. But in the first the calyx is gibbous, or fwelling at the base; in the second it is cylindric, with membranous edges: the first has a sessile down; in the fecond it is stipitate, and the seeds are polished. You will always find it useful, where you can, thus to bring together and compare plants of nearly allied genera, in order to confider well their fimilitudes and differences, and to give you a readmess in making those minute but important distinctions, fo necessary to discrimination in natural tribes, wherein all feems alike to the untutored eye, as the sheep of the flock to the ordinary paffenger: whereas the shepherd knows each by its proper marks, and calls them all by their names.

Of the Sowthiftle, that vulgar weed of the kitchen garden, there are many varieties; the rough and the smooth; with lacerate leaves and simple ones, &c. which I

mention

A Scorzonera hispanica Lin. Blackw. 406.

O Sonchus oleraceus Lin. Curtis, Lond. II. 58. Ger. 292.

mention only that you may not be led to fearch for them as diffinct species; in reality these differences are owing merely to accident and situation.

Hieracium or Hawkwed is a numerous Hieracigenus of this order and fection; the calyx is um. ovate and imbricate, the receptacle naked. and the down fimple and feffile. There are many species wild in this country; one? which is a large plant, on walls and banks and in woods, with a branching stem, the radical leaves oval and toothed, and a smaller leaf on the stalk: and another very common indeed in dry pastures, called Moule-car Hawkweed9, from the long hairs upon the leaves, which are ovate and absolutely entire: this fort throws out runners, and the flowers come out fingly on naked flalks. There are other species, vulgarly called Hawkweeds, which range under other genera, as the Crepis, which differs from Hieracium, in having the calyx only calycled, with deciduous scales.

I shall conclude the first section with Suc-Cichorecory or Endive; which has the calyx calycled, uma sew chaifs between the flotcules on the receptacle, and the crown of the seed mostly sive-toothed and obscurely hairy. Wild Suc-

Hieracium Pilofella Lin. Curtis, Lond. IV. 54. Ger. 638. 2. Park 600. 1, 2.

P Hieracium murorum Lin. Mor. Hist. s. 7. t. 5. f. 54. Ger. 304.

cory' has runcinate leaves, and generally two feffile flowers coming out together: Endive' has folitary, peduncled flowers, and entire leaves, only notched about the edge. Both have flowers of a fine blue; but the first is perennial, and the second only biennial. Curled Endive, though differing fo remarkably from its parent in the leaves, is but a variety of the last.

Carduus. The greater part of the second section, in this first order of the nineteenth class, is occupied by the Thistles, a most untractable genus, not at all adapted to the delicate singers of our lovely Flora. The calyx is all imbricate with thorny scales; and how will she tear this as under, to discover that the receptacle has hairs between the seeds? Yet these two circumstances form the character of the genus; and she must observe that there are some plants commonly called Thisses, which are not of the genus Carduus. For instance, the Com-

mon Way-Thiftle" not having spines to the scales of the calyx, which also is cylindric

<sup>&</sup>lt;sup>7</sup> Cichoreum Intybus Lin. Curtis, Lond. IV. 56-Ger. 284. 1. Park. 7/6. 2. Engl. Bot. 539. Fl. Ruft. 144.

<sup>&</sup>quot;Cichoreum Endivia Lin.

t See Pl. 25. f. 2.

<sup>\*</sup> Serratula arvensis Lin. Curt Lond. n. 63. under the name of Carduus. Fl. Dan. 644. Mor. Hist. st. 7: t. 32. f. 14. Ger. 1173. 4. Fl. Rust. 132. Many of the thistles are admirably figured in that most elegant work entitled English Botany.

in shape, whereas in the Cardui it bulges out at bottom, and the receptacle being naked, is not a Carduus in Linuxus's idea, but a Serratula. So likewife Cotton-Thiftle Y having a honey-combed receptacle, is teparated on account of that circumstance. Indeed the genus would have been too vast and unmanageable, without an attention to these marks, which might sometimes appear otherwise too minute. You have perhaps even heard it faid that the Artichoke "Cynara. is nothing but a Thistle. It differs indeed very little; having a hairy receptacle, only the hairs being stiffer, it may be called briftly; and the structure of the down being the same, they differ principally in the calyx, for the scales in the Artichoke are fcariose or ragged, fleshy, and terminated by a channelled appendicle, emarginate and pointed—a character which you may examine at your leifure at table. If you would speculate on the blue flowers; which being so large, will give a good idea of florets; at the same time that it is also an excellent instance of the order Polygamia-Æqualis, and the Capitate or Headed section of it; you must prevail on your gardener to let fome heads fland long after the time that they should be cut for the table.

The Burdock, whose heads sometimes fas-Arctium,

<sup>\*</sup> Onopordon Acanthium Lin. Curt. Lond. V. 57. Mor. te 30. f. 19. Ger. 1149. 1.

W Cynara Scolymus Line Blackw. 458.

ten themselves to your clothes as you pass, is in the same division with the Thistles: the globoic form of the calyx, together with the hooked tops of the scales which compose it, are the effential characters of the genus. The common wild species x has very large woolly heart-shaped leaves, petiolate, and unarmed.

MID.

Eupatori- Of the third fection, with Discoid, or, as fome call them, naked discous flowers, few are at hand. The banks of rivers and ditches will furnish a species of Eupatorium, a large plant with digitate leaves: usually there are three leaflets to each leaf, which are hairy, and sharply serrate, the middle one the largest; sometimes the side leaslets are wholly wanting, and the leaf becomes fimple: the stalks are lofty, rough, and quadrangular; and bear large bunches of small purple flowers on their tops, with about five florets in each calyx. The characters of the genus are an oblong, imbricate calyx, a naked receptacle; a feathered down, and a very long flyle, divided half way the length.

Bidens.

The fame fituations will produce you the Bidens; which has also an imbricate calyx: but the receptacle is chaffy; the corolla is

iometimes

y Eupatorium cannabinum Lin. Fl. Dan. 745. Mor. Hist. s. 7. t. 13. f. 1. Ger. 711. 2. Common Hemp-Agrimony. See Pl. 25. f. 3. Engl. Bot. 428:

fometimes furnished with one floret alter? nately radiant; and the feeds are crowned with two erect, rugged awns, which being hooked make the feeds adhere to any thing that comes near them. We have two wild species, the trifid, so called from its trifid leaves; with erect feeds, and leafy calyxes: and the nodding a, with lance-shaped, stemclasping leaves, nodding flowers, and erect feeds. The corollas of both are yellow; but those of the last, which is the least common, are most specious.

### THE ORDER POLYGAMIA SUPERFLUA.

The second order of the class Syngenesia, entitled Polygamia Superflua, being scarcely less numerous than the first, is subdivided into two fections, the first containing the discoid, and the second the radiate flowers: there is only one genus in this order with femiflosculous flowers.

Of the first fection, with discoid flowers, Tenaceyou have the Tansy; which you find to have an imbricate, hemispheric calyx; the corollas of the ray, or on the outside, trifid; the others quinquefid; the feeds naked, being only flightly edged: and the recep-

<sup>2</sup> Bidens tripartita Lin. Water Hemp-Agrimony.

Curtis, Lond. IV. 57. Ger. 711. 1.

\*Bidens cernua Lin. Nodding Water Hemp-Agrimony. Curtis, Lond. III. 55. Fl. Dan. 841.

tacle naked. Sometimes in this genus there are no imperfect flowers. Our common Tansy, which not only the kitchen-garden, but dry upland pastures will furnish you with, has bipinnate, or twice-feathered leaves, which are gashed, and serrate about the edges.

Artemi-

Southernwood, the Wormwoods, and Mugwort, all range under the genus Artemisia; which has a calvx imbricate, with rounded, converging scales; naked seeds; and a receptacle, either naked or with few hairs: the flowers have no ray whatever, but are strictly discoid. Southernwood is shrubby, erect, and has fetaceous leaves, very much branched; there is a field or wild Southernwood, with procumbent, wand-like stems, and multifid, linear leaves. Common and Roman Wormwoods and Mugwort have erect herbaceous stems, and compound leaves. The Commone species has the leaves multifid, the flowers subglobular and pendulous, and the receptacle hairy. Roman Wormwood has the leaves many-parted, and downy underneath, the heads of flowers roundish and nodding, as in the other: but

<sup>&</sup>lt;sup>b</sup> Tanacetum vulgare Lin. Fl. Dan. 871. Mor. hift. 6. t. 1. f. 1. Ger. 650. 1.

Artemisia Absinthium Lin. Blackw. t. 17. Get.

Artemisia pontica Lin. Jacq. austr. 1. t. 99.

the receptacle naked. Mugwort s has pinnatifid, flat, gashed leaves, downy underneath: the flowers are borne in simple, recurved racemes, and have a ray of five flowers. Common Sea Wormwood has procumbent stems; many-parted downy leaves, nodding racemes, and three flowers in the

ray.

Gnaphalium, comprehending many wild Gnapha-Cudweeds and the Immortal flowers, or yel-lium. low and white Everlastings, has an imbricate calyx, with the scales rounded, scariose, and coloured; a naked receptacle, and seathered down. There are several species both of yellow and white Everlastings; the most known of the first is common in Portugal, where they adorn their churches with the flowers, which are also fent annually to England: it is supposed to have been brought originally from India i: the leaves are linear-lanced, and fessile; the flowers are borne in a compound corymb, on elongated peduncles; and the stem is fubherbaceous. One of the latter k is very common in the gardens, and is originally of North America; this has leaves like the former, sharp-pointed, and alternate; the stems herbaceous, and branched above, the flowers in corymbs, with level tops. This

<sup>&</sup>lt;sup>8</sup> Artemisia yulgaris *Lin*. Blackw. t. 431. Ger. 1103. 1.

<sup>\*</sup> Gnaphalium margaritaceum Lin.

has a very creeping root; and the stalks and leaves are woolly: the silvery calyxes, as well as the golden ones, of the former, if gathered before they are too open, will continue in beauty many years.

Xeranthemum.

Xeranthemum, or Eternal flower, has an imbricate calyx, with the inner scales membranaceous, shining, and forming a fet of coloured rays to crown the flower; the receptacle is mostly naked; and the down is either briftly or feathered. Annual Xeranthemum<sup>1</sup> is an exception to the general character, in having a chaffy receptacle; it is also the only one which has a down of five brifles: it is herbaceous, has lanceshaped spreading leaves; the outside florets have a fimple stigma, with a naked feed; those in the middle have a sub-bifid stigma. The colour of the corolla is either purple or white. There is a fort from the Cape with vellow flowers ".

Tumlago. The second division of this order, with Radiate slowers, is much the largest. Tuffilago or Colt's-foot has a cylindric calyx, with equal scales, from sisteen to twenty in number, as long as the disk of the flower, and a little membranous; a naked receptacle, and a simple or hairy down. Common wild Colt's-foot has angular leaves, rather

<sup>&</sup>lt;sup>1</sup> Xeranthemum annuum Lin. Mill. Illustr. Jacq. austr. 4. 388.

m Xeranthemum speciosissimum. Seba 2. t. 43. f. 6.

"Tushlago Farfara Lin. Curtis, Lond. II. 60. Ger.
811. Park. 1220. Engl. Bot. 429.

heart-shaped, with slight indentations about the edges, underneath white; and one yellow flower on a scape, which is imbricate or covered with scales. Butter-bur has vast leaves shaped much like those of the Colt'sfoot; many (from ten to twenty) purplish flowers, collected into an ovate thyrie, on the top of a purplish scape set with scales of the fame colour: there are fometimes from two to fix imperfect, white, ligulate florets, with scarcely any corolla, among the others. You will not be able to examine all the specific characters of these two plants at once; for the naked stem which bears the flowers pushes up alone very early in the spring; and the leaves do not succeed till the flowers are past.

Senecio, or Groundfel, is a very numerous Senecio. genus p, having a cylindric calycled calyx, with the scales sphacelate or seeming mortified at top; a naked receptacle, and a simple down. Most of the species have radiate flowers; eight of them however have not; and among these is the Common Groundsel, so vulgar a weed in kitchen-gardens. Stinking Groundsel, a plant not very unlike this, has however radiate corollas, with the semi-

Cc3 florets

<sup>°</sup> Tuffilago Petasites Lin. Curtis, Lond. II. 59. Ger. 814. Engl. Bot. 431.

Fifty-nine species.
Senecio vulgaris Lin. Curt. Lond. I. 61. Ger.

r Senecio viscosus Lin. Dill. elth. t. 258. f. 336. Engl. Bot. 32.

florets of the ray revolute; the scales of the calvx are loose; and the leaves are pinnatistic and viscid. This grows in hedge-rows and on heaths, and is a much taller plant than the last.

Common Ragwort' has also radiate corollas, with the ray however not revolute but expanding: the stem of this is erect; the leaves pinnatifid, approaching to lyrate, with the divisions a little jagged. This is very common by road-fides and in pastures. The gardens have a purple African Groundfelt from the Cape; an annual plant with a yellow difk, and purple rays: it agrees with Ragwort in having radiate corollas with the ray expanding; the leaves are pinnatifid, equal, and very spreading, with a thickened recurved margin; and the scales of the calyx are thinly ciliated. A fingular plant of this genus came up one year in my garden, which I took at first to be a new species; but, on more accurate examination, it proved to be a hybridous plant or mule, produced from this and the Common Groundsel: it had the radiate flowers of the one, small indeed, and slightly tinged with purple, and the herb of the other; being annual, and producing no feed, this variety passed away with the season.

t Senecio elegans Lin. Comm. Hort. 2. t. 30. Seba Muf. 1. t. 22. f. 1. Curt. Mag. 238.

The

<sup>&</sup>lt;sup>5</sup> Senecio Jacobæa *Lin*. Mor. Hist. f. 7. t. 18. f. 1. Ger. 280. 1. Park. 668. 1. Fl. Rust. t. 85.

The two genera of After and Golden-rod After. furnish abundance of flowers that enliven the autumnal feafon, and continue till the feverity of frost puts an end to them. They both agree in an imbricate calyx, a simple down, and a naked receptacle: but the inferior scales in the calvx of the Aster are spreading, and have a ragged appearance; whereas in the Golden-rod they are close: all the species also of the Aster have more than ten femi-florets in the ray, but the Golden-rods have only about five or fix remote ones. Some of the Afters are shrubby, but most of them are tall herbaceous plants, dying down to the ground, at the approach of winter, and rifing again from the same root the ensuing fpring: many are confounded under the vulgar title of Michaelmas Daifies. The Amellus, or purple Italian Starwort", is one of the lowest species, but has large purple flowers, growing in a corymb on naked peduncles, with the scales of the calvx obtuse: the leaves are lance-shaped, obtuse, rugged, entire about the edges, and marked underneath with three nerves. The greater part of the perennial American Afters have scaly peduncles; some have entire, and others have ferrate leaves; hence a convenient subdivision of the genus: there are however some few species with serrate leaves

<sup>&</sup>quot; After Amellus Lin. Jacq. austr. 435. Virg. geor edit. Mart. p. 368. Cc4

and naked smooth peduncles. Large flowering or Catesby's Starwort, is one of the handsomest; the slowers being large and of a deep purple; the calyx is ragged; the peduncles are scaly, and sustain only one flower; the leaves are quite entire, tongue-Thaped, and clasp the stem. Chinese After is an annual plant, with ovate, angular leaves, toothed about the edge, and petiolate; the flowers terminate the branches. and have spreading leafy calyxes. The variety of colour, and fize of the corolla, have made this species very generally cultivated: their being frequently double, will not induce you to mistake a double radiate for a natural ligulate flower: which, to an unobserving eye, it perfectly resembles. The falt-marshes on the sea-coast of Europe furnish one species, called Sea-Star-wortx: this. has lance-shaped, entire, slethy, smooth, leaves; the branches are unequal; and the flowers in a corymb. o and to late and the

Solidago. Of the Golden rods we have only one European species, unless we distinguish the Wellh Golden-rod, which seems but an

humble variety. The stem is a little slexuose or winding; and the slowers grow in
erect, crowded, panicled racemes. The
Welsh variety has the leaves a little hoary
underneath, and roundish clustered spikes
at the top of the stalk, with larger flowers
appearing earlier than the common sort:
in losty situations and dry soils, a stem will
sometimes produce one flower only. North
America has surnished abundance of species,
whose golden racemes of slowers mix happily with the purple corymbs of the Asters;
and thus they jointly enliven plantations of
shrubs in the latter season.

Inula, of which Elecampane is the lead-Inula. ing species, has the following characters—a naked receptacle; a simple down; and the anthers ending at the base in two bristles: this structure of the anthers is unique—the cylinder is composed of five smaller linear anthers, each ending in two bristles, of the length of the silaments. The true Elecampane is distinguished by its large, stem-clasping, ovate, wrinkledleaves, downy underneath; and by the ovate form of the scales of the calyx. The stalks are three feet high, and divided towards the top into several smaller branches, each of which is terminated by one large yellow flower. The

<sup>&</sup>lt;sup>a</sup> Inula Helenium Lin. Fl. Dan. 728. Mor, Hift, f. 7. t. 24. f. laft., Ger. 793.

Flea-banes middle b and less are of this genus: the first is common in moist meadows. and has stem-clasping, oblong leaves, hollowed next the petiole; a villous stem terminated by yellow flowers in panicles; and the scales of the calyx bristly. The second has also stem-clasping leaves, but waved; prostrate stems; and subglobular flowers, easily known by the shortness of the ray. The place of this is by road-fides, and where water stands in winter.

cum.

Doroni Doronicum or Leopard's bane, a wild plant of the Alps, and now common among the perennials of the garden, has the scales of the calyx in two rows, equal, and longer than the disk, the feeds of the ray naked or destitute of down; those of the disk crowned with a simple down; the receptacle naked. The common species, above alluded to d, has heart-shaped leaves, slightly indented about the edge, and obtute at the end; those at the root petiolate, those above stem-clasping. The stalks are channelled and hairy, near three feet high: these put out a few fide branches, each of which is terminated by a large yellow flower. A fecond species' has ovate, acute leaves,

flightly

d Doronicum pardalianches Lin. Mill. fig. 128. Engl. Bot. 630. Jacq. austr. 4. t. 350. and Pl. 26. of this work. \* Doronicum plantagineum Lin,

flightly indented, and alternate branches. A third has a naked, fimple stem ending in one flower: and these make up the whole

Tagetes has a one-leafed, five-toothed, Tagetes, tubular calyx; five permanent florets to the ray; the feeds are crowned with five erect awns; and the receptacle is naked. French and Africanh Marigolds, two of the gaudy annuals of the flower-garden, are of this genus. The first is distinguished by a subdivided spreading stem; the second, by an crect, simple stem, with naked, one-slowered peduncles. Of both these, as you well know, there are many varieties in colour, from pale brimstone to deep orange; and the more double they become, so much the more does your gardener value himfelf on his skill or good fortune.

Chryfanthemum, fo named from its golden- Chryfancoloured flowers, is known by its hemi-themum. fpheric, imbricate calyx, formed of close scales, the inner ones gradually larger, and the inmost membranous or chaffy; there is no down to the feeds, but they are only edged or margined; the receptacle is naked. Some of the species are improperly termed Chrysanthema, having white rays to the flowers: of these we have an instance in

h Tagetes erecta Lin.

f Doronicum Bellidiastrum Lin. Jacq. austr. 4.

<sup>2</sup> Tagetes patula Lin. Curt. Magaz. 150.

the Ox-eye Daifyi, a plant common among standing grass in meadows, and having oblong, stem-clasping leaves, sawed above, and toothed below. Gorn Marigoldk, which is a weed among the corn in fandy lands. has yellow rays, and stem-clasping leaves, jagged above, and toothed below; they are smooth, and of a glaucous hue. Lest you should think the colour of more importance than it really is, I will put you in mind, that the species so commonly cultivated in flower-gardens under the name of Chryfanthemum creticum, has both yellow and white rays: these flowers are esteemed in proportion as they deviate from nature; but the plant may always be known, by the pinnate gashed leaves, growing broader towards the Bunend:

Matrica- The three genera of Matricaria, Cotula, and Anthemis, are nearly allied. The first has a hemispheric, imbricate calyx, with the marginal scales solid, and rather acute: the feeds have no down; and the receptacle is naked. The fecond has a convex calvx: the florets of the disk quadrifid; those of the ray have only a germ with its style and stig-

<sup>1</sup> Chryfanthemum coronarium Lin. Mor. t. 4, f. 2, 2.- C. indicum Curt. Magaz. 327.

mas, without any corolla: there is no down; but the feed is margined: and the receptacle is naked, or nearly fo. The third has a hemispheric calyx, with the scales nearly equal; more than five semiflorets in the ray; no down; and a chaffy receptacle. There are plants vulgarly known by the name of Mayweed or Camomile, in each genus. Common Fever-few also is a species of Matricaria: the leaves are compound and flat, the divisions are ovate and gashed, and the peduncles are branched: it grows upon banks, has a strong unpleasant scent, the leaves are of a yellowish green, and the rays of the flower are white: admitted into gardens, it has generally double flowers. Common or true Camomile" is an Anthemis; and Anthehas compound pinnate leaves, the divisions mis. linear, acute, and a little villous. It fometimes covers a considerable extent of ground on dry fandy commons, trailing along, and putting out roots from the stalks; its agreeable odour betrays it as we tread upon it: that which is found in gardens, has usually lost all character by cultivation.

Achillea or Milfoil has an oblong-ovate Achillea imbricate calyx; from five to ten semiflorets in the ray; no down; and a chaffy recep-

tacle

m Matricaria Parthenium Lin. Fl. Dan. 674. Ger. 652. 1.

n Anthemis nobilis Lin. Blackw. 298. 1 Ger. 755.4.

tacle. Common wild Milfoil or Yarrow has bipinnate naked leaves, the divisions of which are linear and indented; the stems are furrowed above. It is a vulgar plant in pastures, and particularly by way-sides; for it seems to delight in being trod upon, and in such places spreads itself abundantly. The usual colour of the flower is white, but it sometimes varies to a sine purple. Other foreign species are yellow.

The four remaining orders of this class being much less numerous than the two which we have already examined, there is not the same occasion for subdivisions; and accordingly Linnæus has not made any.

# THE ORDER POLYGAMIA FRUSTRANEA.

The third order of Frustraneous Polygamy comprehends no more than seven genera, Helian-from which I shall select two—Helianthus and Centaurea. The first has an imbricate calyx, rather squarrose, or having a ragged appearance from the spreading of the tips of the scales; a two-leaved or two-awned

crown

Achillea Millefolium Lin. Curt. Lond. n. 63. Fl. Dan. 737. Mor. Hist. s. 6. t. 11. f. 6, 14. Gerd 1072. 2. Fl. Rust. 123. A. Ptarmica, Curt. Lond. V. 60. r. ford. 2011

crown to the feeds; and a flat chaffy receptacle. Every species of this genus is a native of America alone; and on the discovery of the New World, some of them were vaunted as miracles of nature, though they are now become so common as almost to be difregarded. The annual Sun-flower p however, it must be acknowledged, is a slower of wonderful magnificence, and owes the diminution of regard to the facility of its propagation: the specific characters are-heartshaped leaves, marked with three principal nerves; peduncles thickening immediately under the calyx; and the flowers nodding. No flower is more proper than this, from its great fize, to give you an idea of a compound flower, and its component floscules, or florets and femiflorets; only you will remember not to expect feeds from those of the ray, that being the character of the order. Perennial Sun-flower is yet more common than the last, because it spreads much at the root, and requires no care in the cultivation: the inferior leaves of this are heart-shaped and three-nerved, but the upper ones ovate. The flowers, though much smaller than those of the last, are yet the largest and most fightly of the perennial forts, and the same plant produces abundance of them. You will be on your guard against double flowers. The perennial forts feldom

P Helianthus annuus Lin. Mill. Illustr.

<sup>&</sup>lt;sup>q</sup> Helianthus multiflorus Lin. Pluk. phyt. 159. f. 2. Curt. Mag. 227.

produce feeds in our climate: whereas the annual, which can be propagated no otherwite, has them in plenty. Jerusalem Artichoke is also a species of Helianthus; the leaves are ovato-cordate, or egg-shaped, only hollowed at the base; they are also marked with three principal nerves: this frequently does not even flower, but it is cultivated not for the fake of these, but the tuberous or knobbed roots, refembling in form the potato, but in taste an artichoke bottom. There is a species which has the common or trivial name of giganteus or giant: Jerusalem Artichoke justly merits the same title, for I have measured stems of it twelve feet high.

rea.

Centau- Centaurea is a most numerous genus of the fame third order, containing no lefs than fixty-fix species. The corollas of the ray are funnel-form, or tubular, longer than those of the disk, and irregular; the down is simple; and the receptacle has bristles between the florets. This otherwise unwieldy genus is commodioufly subdivided into six fections, by the variations of the calyx, which you observe make no part of the generic character. I. Plants commonly called Jaceas, with smooth, unarmed calyxes. II. Cyanuses, with the scales of the calyx serrate and ciliate. III. Rhaponticums, with dry, scariose scales, like chast, or as if parched. IV. Stoebes, with the spines of the calyx

Helianthus tuberosus Lin. Jacq. Hort. 2. t. 161. palmate.

palmate. V. Calcitrapas, with the spines of the calyx compound or fubdivided. VI. With the spines simple or wholly undivided. To the first section belongs the Sweet Sultan', which has a roundith calyx with ovate fcales; and lyrate leaves, indented about the edge. It is an annual plant, with purple flowers, of a sweetness so powerful as to be offensive to many persons; they come out fingly on long naked peduncles, and frequently vary to flesh colour and white. There is a yellow Sweet Sultan, which differs not only in the colour of the flowers, and in having a milder odour, but also in having the edges of the leaves ferrate: it is doubtful however whether it be a distinct species from the former. The Great or Officinal Centaury is also of this section: the scales of the calyx are ovate; the leaves are pinnate; the divisions ferrate and decurrent. The plant is large and tall, and the flowers are purple.

Of the fecond fubdivision we have three plants commonly wild, and one little less common in gardens. Common or Black Knap-weed<sup>1</sup>, perhaps more properly Knob-Weed, which the country people in some places call Hard-heads, is found in almost all pastures, and is one instance, among many

Centaurea moschata Lin. Mor. Hist. s. 7. t. 25. f. 5.

t Centaurea Centaureum Lin. Blackw. 93.

<sup>&</sup>quot; Centaurea nigra Lin. Ger. 727. 1. Park. 468. 1. Engl. Bot. 278. Fl. Rust. 130.

others, of the vile weeds which are suffered to occupy grafs fields with impunity; the scales are ovate, with erect, capillary cilias: the leaves are lyrate and angular; and the flowers are flosculous. Great Knapweed has pinnatifid leaves, with the lobes lanceolate. This grows in corn fields and on balks. The flowers of both are red; but those of the latter are much the largest and most specious. Blue Bottlew, the third wild plant of this fection, which every body knows for an univerfal weed among corn, and whose beautiful blue colour would have attracted regard, had it been rare, has linear leaves, which on the stem are quite entire; towards the ground they are broader, indented about the edges, and fometimes pinnate. Mountain Blue-bottle\* which has migrated from the Swifs mountains into our gardens, is very nearly allied to this, but its flowers are much larger: the leaves also are lance-shaped and decurrent, and the stem is quite simple; whereas the wild fort is branched. Carduus Benedictus, or Bleffed Thiftley, is an instance of the fourth section: it has doubly spined, woolly calyxes, furnished with an involucre; the leaves are femi-decurrent, in-

Centaurea Scabiofa Lin. Engl. Bot. 56.

W Centaurea Cyanus Lin. Mor. t. 25. f. 4. Ger. 732. 2. Park. 482. 2. Engl. Bot. 277. Fl. Ruft. 111. \* Centaurea montana Lin. Mill. fig. 114. Curt Mag. 77. Pl. 27. f. I.
y Centaurea benedicta Lin.

dented, and prickly: this is a small annual plant with yellow flowers. We have a wild species of this section—the Star-thistle, growing by road-sides, and in dry pastures, but not every where: it has sessile flowers, with the calyxes rather doubly spined: the leaves pinnatisid, linear, and toothed; the stem hairy, and much branched: the spines of the calyx are white, and the flowers red. Of the other sections none are likely to rocet your eye; indeed the roughness and vulgarity of their habit, in which they much resemble Thistles, have occasioned the numerous species to be little cultivated.

#### THE ORDER POLYGAMIA NECESSARIA.

The Marigold of the kitchen garden will Calenfurnish a familiar instance of the fourth dula. order—Polygamia Necessaria. The genus is known by a calyx of many equal leaves; by the seeds having no down, and those of the disk being membraneous; and by the receptacle being naked. The common or officinal species is distinguished in having all the seeds boat-shaped, bent inwards and muricate.

<sup>&</sup>lt;sup>2</sup> Centaurea Calcitrapa *Lin*. Ger. 1166. 1. Engl. Bot. t. 125.

a Calendula officinalis Lin. Mill. Illustr. Pl. 27.

#### THE ORDER POLYGAMIA SEGREGATA.

or perianth common to the whole flower, there is a fecondary one, including feveral floscules, or sometimes one only; this forms one character of the genera. Echinops has only one flower to each partial calyx: besides this, the floscules are tubular, and complete; the seeds have an obscure down; and the receptacle is bristly. Common Globe thistle b is so called from the flowers growing in globular heads: the leaves are sinuous and pubescent, the jags ending in spines; the flowers are blue, and sometimes white.

#### THE ORDER MONOGAMIA.

We have now done with the natural tribe of compound flowers, but there remains yet one order of the class Syngenesia, in which the flowers are totally different, except in the common character of the union of the five anthers; they are simple, like the flowers of other classes, or have only one corolla inclosed within the calyx, without any common perianth. The Violet will furnish you with a number of notorious examples of this order. All the species,

Viola

Echinops sphærocephalus Lin. Mill, Illustr. & Pl. 28.

which are twenty-eight, agree in a fiveleaved calyx; a five-petalled irregular corolla, produced into a horn or spur behind; and in a three-valved, one-celled capfule, above the receptacle, or inclosed within the calvx. The Sweet Violetc, that scents the banks, hedges, and borders of woods, in the fpring, with its fragrant purple flowers, is one of those which have no stalks, except the scape which supports the flower. and the runners by which they are propagated; the leaves are heart-shaped. The corollas are fometimes white, and the gardens boast a large double variety. This is one of the few wild plants, whose allowed merit has fecured it a place in every cultivated spot. The latter species without scent. commonly called Dog Violet d, is one of the caulescent or stalky kind, the more adult stems ascending; the leaves are heartshaped, but drawn to a point at the end: the corolla is paler than that of the Sweet Violet, and, having leaves proceeding from a stalk, cannot be mistaken for that in which they grow immediately from the root, even if the odour were not attended to. Heart's-ease or Pansiese, the universal

Viola odorata Lin. Curtis, Lond. I. 63. Ger. 850.

d Viola canina Lin. Curtis, Lond. II. 61. Ger. 851. 65 Engl. Bot. 620.

e Viola tricolor Lin. Curtis, Lond. I. 65. Fl. Dan. Dd 3

favourite of the more simple unrefined ages is one of those which have pinnatified stipules, and an urceolate or pitchershaped stigma: it has also a three-cornered, diffuse stem; and oblong gashed leaves. Such are the characters of a plant, which every child becomes acquainted with as soon as he can walk into a garden: but it is not therefore wholly useless to mention it, because it may at least serve to explain several terms to you, and to assist you in the examination of plants with which you are not so well acquainted.

When we compare the diminutive and almost colourless Pansy, which we find wild among the corn, with the ample rich-coloured corolla, that boasts the tissue of velvet, such as we see in some curious gardens; we cannot but allow that human art has made a considerable improvement; and we survey it with the more pleasure because it is not at the expence of the natural characters of the flower; and you may enjoy it both as a botanist and a florist \*.

Impatiens. That beautiful flower called Balfam is of this order. Linnæus names the genus

623. Ger. 854. 1. This has numberless provincial names, bearing some allusion to love.

"Yet markt I where the bolt of Cupid fell.

"It fell upon a little western flower,

"Before milk white, now purple with Love's wound, "And maidens call it Love in Idleness."

'And mardens call it Love in Idleneys."

Midfum. Night's Detain, II. 2.

\* Perhaps the Garden Pansy may rather derive its origin from the grandistora or Great Yellow Violet.

Impatiens,

Impatiens, because the capsule when ripe is impatient of the touch, eafily burfting, and thus throwing out its feeds. It has an irregular corolla of five petals like the violet, when it has not been improved into beautiful duplicity by culture; but the calyx is two-leaved; the nectary or horn is cucullate or cowl-shaped; and the capsule is five-valved. True Balfam, or, more properly, Balfamine f, has the leaves lanceshaded, those on the upper part of the plant alternate; the flowers come out three or four together, from the joints of the stalk, only one on each flender peduncle; and the nectary is shorter than the flower: the varieties of colour-white, red, purple and variegated, are well known. That which comes from the East Indies has larger, finer flowers than what comes from the West. most beautifully variegated with scarlet and white, or purple and white. We have a wild species called Yellow Balfam, and also by the familiar names of Quick in hand, or Touch me not g: one long ilender peduncle comes out from the axils, which fubdivides into feveral others, each fustaining a yellow flower; the leaves are ovate; and the stem swells at the knots. This is a local plant, being observed only or chiefly

THE REPORT OF SHIPLEY STATES

# LETTER XXVII.

adjusting the Manthaland and a gentlement

The state of the s

THE CLASS GYNANDRIA.

May the 1st, 1777.

RENEW our pursuit as early as posfible, my dear cousin, in order that I may be able to accomplish my purpose of completing our original scheme during the

course of the present season.

The twentieth class, which falls now under our confideration, is entitled Gynandria, from a circumstance peculiar to it, which is that of having the stamens situated upon the style itself. You have remarked, that in every class hitherto examined, these two parts are entirely independent, fo that we can at any time remove the one from a flower, and leave the other; but in the class Gynandria this is not permitted us; the stamens usually growing out of the piftil itself; but in some cases upon a receptacle, produced or lengthened in form of a style, which bears both pistil and stamens. This class has nine orders, founded on the number of stamens in the flower of each; the genera are 33, and the species 275.

The first order, called *Diandria*, from there being two stamens only to the flowers in it, is perfectly natural: that is, contains

a tribe of plants agreed upon by all the world to be in strict alliance; or such, as when an eye properly informed has feen one of them, it immediately refers any of the others to the same tribe, clan, or family, as foon as they occur. Indeed the alliance between the greater part of these plants is fo strict, that some nomenclators have been induced to refer them to one genus, or one family properly so called; for the genera differ hardly in any thing else from each other but in the shape of the nectary. Some former nomenclators had established the genera upon the roots, which are certainly the part least proper for this purpose, because you cannot examine the character without destroying the plant. But they were induced to it, from the fingular form of the roots in this tribe: which in some species are a pair of folid bulbs; in others a fet of oblong fleshy bodies tapering to the extremities, and spreading out like the fingers, whence they have the name of palmate or banded.

Having said so much of this tribe, it is almost time, you think, to be acquainted with the singular personages that compose it. The sar greater number of them, then, have the common appellation of *Orchis*, a name I am persuaded you are not wholly unacquainted with.

Orchis.

unacquainted with.

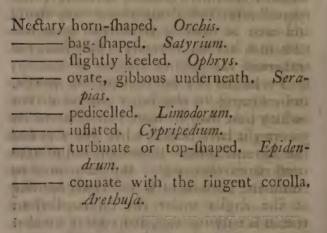

Take one of these flowers, of any sort you can meet with; or, if no species is yet

in blow, you will not have long to wait for fome of them. You will find an oblong, writhed germ, below the flower, which has no proper calyx, but only spathes or sheaths: the corolla is made up of five petals, the two innermost of which usually join to form an arch or helmet over the top of the flower: the lower lip of the corolla forms the nectary, taking the place of the pistil and a sixth petal: the style adheres to the inner edge of the nectary, fo that, together with its stigma, it is scarcely diftinguishable; the filaments are very short, and each of them is terminated by an anther that has no covering, but has the texture of the pulp of oranges or lemons; each is lodged in a cell opening downwards, and adhering to the inner margin of the nectary; so that without this information you might have been at a loss where to find the stamens, unless they happened to have burst from their cells: the germ in time becomes a capfule, of three valves, opening at the angles under the carinated ribs; within is only one cell, and a great number of small, irregular seeds, shaped like sawdust, are affixed to a linear receptacle on each valve. I have been more particular on the character of this tribe, because the flowers have rather a strange and unusual appearance, owing to the fingular position of the parts of fructification. There is a connexion between this and the liliaceous tribe:

tribe; both having but one lobe to the feed, fucculent roots, entire leaves, and a naked corolla; they differ however in the number of stamens, the form of the corolla and nectary, the situation of the germ, the number of cells in the capfule, the shape and arrangement of the seeds; this tribe also bears its slowers on a spadix, and has bractes interposed between them.

The principal genera of this tribe are thus

distinguished:

The Orchis is the largest genus, there being no less than fifty species, of which eleven are found wild in England. The greater number have double bulbs; in the rest the roots are either palmate or fasciculate.

Of those with double bulbs woods and bushy passures produce the Butterfly Orchis,

chish, which has the lip of the nectary lance-shaped and quite entire; the horn very long; and the petals foreading out wide. The flowers of this smell sweet, particularly in an evening, and very early in the morning. There are only two, or at most three large leaves: the stem is a foot or eighteen inches high: the spike is long, but the flowers are thinly spread in it; the bractes are large, and the length of the germ; the flowers are of a greenish white; the spur is twice as long as the germ, very flender, and transparent enough for you to discern the nectar through it. There is a smaller variety, but differing no otherwise than in size.

Pyramidal Orchisk, found in passures where the soil is chalky, is another of those which have double bulbs: the lip of the nectary is two-horned, trisid, the segments nearly equal, the middle one being rather the narrowest; all of them are quite entire; the horn, or spur, is cylindric, slender, and longer than the germ; and the petals are nearly lance-shaped. This is an elegant species, having six or more radical

h Orchis bifolia Lin. Fl. Dan. 235. Vaill. par. t. 30. f. 7. Mor. Hift. f. 12. t. 12. f. 18. Ger. 211. 2. Park. 1351. 7. Engl. Bot. 22.

Hallier fays linear.

k Orchis pyramidalis Lin. Raii fyn. t. 18. Jacq. Auftr. t. 266. Vaill. t. 31. f. 38. Hall. helv. t. 35. 1. Ger. 210. 4. Park. 1349. 4. Engl. Bot. t. 110.

leaves; the stem a foot, or eighteen inches high; the spike of flowers short, of a broad conical form, and very thick set at first; the bractes at least equal in length to the germs, lance-shaped, and ending in a point;

the corolla bright purple.

Two of the most common forts with double bulbs, are called Male and Female Orchis foolishly, because there is no distinction of fexes; and therefore these names are only calculated to mislead. The ifirst differs from the fecond in having the outer petals more acute, and longer; and the middle lobe of the lip bifid and longer than the fide ones; it is also a much larger plant, with broader leaves, usually spotted. The second " has the lip of the nectary crenulate, or flightly notched on the fides, trifid, with the middle lobe emarginate, and the petals obtuse and linear. The height of this seldom exceeds feven or eight inches; the leaves are half an inch broad; and the spike is cylindric, with few flowers; the bractes are coloured, and a little longer than the germs; the petals forming the helmet converge, and are marked with green parallel lines; the middle of the lip is spotted, and the fides are rolled back; the horn is equal to the germ, with the end emarginate;

m Orchis morio Lin. Curtis, Lond. III. 59. Vaill.

t. 31. f. 13, 14. Ger. 208. 2. Park. 1347. 4.

<sup>&</sup>lt;sup>1</sup> Orchis mascula *Lin*. Curtis, Lond. II. 62. Vaill. t. 31. f. 11, 12. Ger. 208, 1. Park. 1346. 1. Engl. Bot. 631.

the most common colour of the corolla is deep purple, but it varies to rofe-coloured, and even white. The first is a foot, and even eighteen inches high; the leaves an inch and half broad; the spike handsome. long, and thin fet with flowers; the bractes about the same length with the germs, purple and lance-shaped; the petals that form the helmet loofe, not converging, they are purple, with lines of the same colour; the edges of the lip are bent downwards, the colour pale purple, with deeper spots at the chaps; the spur is straight, thick, as long as the germ, or longer, dilated and compressed at the end. The colour of the corolla varies, even to white. This grows in meadows; and the roots make excellent Salep. The second affects open dry pastures. Thus you have abundant means of distinguishing these two species of Orchis from each other; and the roots are a sufficient mark of distinction from two others, no less common, which we shall examine prefently. In the mean time there is a small but pretty species with double bulbs, which we must not pass by. It grows chiefly on dry exposed chalk hills, and is called Dwarf Orchis": the lip of the nectary is quadrifid, and white dotted with purple; the horn is obtufe, and

Orchis ustulata Lin. Fl. Dan. 103. Hall. t. 28. 2.
 Vaill. t. 31. f. 35, 36. Mor. t. 12. f. 20. Ger. 207.
 Park. 1345. Engl. Bot. 18.

the petals are distinct. The height is from four to seven inches: there are several leaves next the ground but sew on the stem: the spike is short and close set; the bractes are shorter than the germ; the helmet is pointed, and of a deep purple on the outside: within, the petals are marked with lines and dots of purple; the horn is a little bent, and

not half the length of the germ.

Two very common species with palmate, or handed bulbs, are the broad leaved and spotted Orchis, generally found in moist meadows. The first has the roots rather palmate and straight; the horn of the nectary conic, the lip three-lobed, and turning back on the fides; the brackes large, and longer than the flowers, fo as to give the spike a leafy appearance. The horn is shorter than the germ, bent and obtuse. The colour of the corolla is purple, varying to rose and white. The second has narrower leaves, and a folid stem, whereas that of the first is hollow; it is also higher, and flowers later; the leaves of both are spotted with black, but this more generally; the bractes are fmaller and narrower; the corolla of a paler purple; the lip of the nectary is deeper cut, the fide lobes are

<sup>°</sup> Orchis latifolia *Lin*. Curt. Lond. V. 65. Mill. Illustr. Fl. Dan. 266 Hall. 32. 2. Vaill. t. 31. f. 1-5. Ger. 220. f. 1, & 22 . f. 3:

P Orchis maculata Lin. Hall. t. 32. 1. Vaill. t. 31. f. 9, 10. Ger. 220. 2. Park. 1357. 3. Engl. Bot. 632. notched

notched, the middle one very narrow, quite

entire, and drawing more to a point.

I shall mention only one species more of Orchis, and that also has palmate roots: it is found in pastures, but by no means so common as the two last: you may call it long-spurred, or sweet Orchis, and you will know it by the great length, and slimness of the spurs: the lip is trisid, equal, slightly notched, and obtuse; and the side petals spread out very wide. The stem is leasy, and grows to the height of eighteen inches; the bractes are sharp-pointed, and of the length of the germ; the corolla is purple, and all of one uniform colour; the smell is strong, but, in some circumstances, sweet.

The fecond genus of this natural tribe is Satyrium the Satyrium, which, instead of the horn, or spur, has a short, bag-form, or double-instant nectary, at the back of the flower. This is a much less numerous genus than the last, having only eight known species. Of these I shall select two; Lizard Satyrion, and Frog Satyrion, commonly called Frog Orchis. The sirst is found in chalky pastures, but rarely; and has been rendered

Ger. 224. 9. Park. 1358. 9. Engl. Bot. t. 94.

more rare by the diligence with which it has been fought after, to transplant it into gardens, where it feldom continues long. this tribe being generally abhorrent of culture. It has double undivided bulbs: lance-shaped leaves; the lip of the nectary trifid, the middle lobe linear, oblique, extremely long, flaunting like a ribband, and feeming, as it were, bitten off at the end. It is a very large lofty plant, from eighteen inches to three feet in height; the leaves also are half a foot long and more, and three inches broad; the spike has many flowers, and, by age, grows very long and becomes bent; the bractes are slender, acute, greenish, and twice as long as the germs; the colour of the corolla is greenish without, and rusty within, with purple lines and spots: the flower has a strong goatish smell.

Frog Orchis is much more common in meadows. The bulbs of this are palmate, the leaves oblong and obtuse; the lip of the nectary trisid, with the middle lobe obsolete, or so small as to be obscure. This is a much lower and smaller plant than the former, not being above seven or eight inches high: the radical leaves are broad and ovate; those on the stem, which are sew, lance-shaped; the spike is rather thin set with slowers: the braces are lance-shaped, and longer than the germ: the helmet is almost closed, pale green, with a purple line dividing the petals; the lip is the state of the series of th

vellow, hangs down straight, and grows broader towards the end; the whole corolla

becomes dusky red with age.

The third genus of the Orchis tribe is Ophrys, entitled Ophrys: it has no horn or bag at the back of the corolla, but one petal longer than the rest, hanging down and marked underneath with a longitudinal rifing, called the keel. This it is which in some species takes the form of an infect fo exactly,

as to appear real at a certain distance.

One species, called Common Twaybladet, or Twyblade, from its having always two leaves, and no more, is frequent in woods and bushy pastures. It has fibrous roots, two ovate leaves, and the lip of the nectary bifid. The stem is eighteen inches high, rather rough or hairy, and naked, except the two large leaves in the middle, between the root and the spike, which is sometimes fix inches long, and has forty flowers, thin fet on short peduncles; the bractes are very fmall, broad, and sharp-pointed; the germ is round, and thicker than in any other of the species; the corolla is of a greenish yellow.

The latter end of fummer and beginning of autumn flowers the Spiral Ophrys, commonly called Triple Ladies Traces"; you

will E e 2

<sup>&</sup>lt;sup>t</sup> Ophrys ovata Lin. Curtis. Lond. III. 60. Ger. 403. I.

Ophrys spiralis Lin. Curtis, Lond. IV. 59. Fl. Dan. 387. Park. 1354. 3. Engl. Bot. 541.

will find it on heaths and dry pastures: The root consists of oblong aggregate bulbs, the stem is a little leasy, the slowers are spiral, and all on one side of the stem; and the lip of the nectary is undivided and slightly notched. This is a small plant, seldom above sive or six inches high, though in a less dry soil it will rise to a foot; it has four or sive leaves next the ground; the spike is long and slender, having twenty slowers, white within and yellowish without; the brackes are not flat, but hollow, and longer than the germ; the three outer petals of the corollas are glued together; the lip is roundish and ciliate. It has a pleasant odour.

But the most interesting and admired species of this genus are the Fly and Bee Orchises, which agree in having two roundish bulbs, and a leasy scape or stem. Linnaus thinks the Fly and the two Bees' not to be specifically different, but in this I cannot agree with him. Fly Ophrys or Orchis' has the lip of the nectary quadrifid; in the common Bee Orchis' it consists of five lobes, which are deslex or bent

Ophrys infectifera Lin. And the state of the line of t

<sup>\*</sup> Orchis muscislora Halleri, 1265. t. 24. 2. Ophrys insectisera myodes Lin. Oph. muscisera Huds. Engl. Bot. 64. Vaill. t. 31. f. 17, 18. Ger. 213. 6. Park.

downwards;

downwards; and in the green winged Bee Orchis, now called Spider Ophrysy, it is roundish, entire, emarginate, and convex. But besides this character from the lip of the nectary, the Fly is a stiffer, straighter plant than the Bee, not so leasty, and having the flowers thinner fet; in other respects they are much alike, except in the corollas, which are widely different: that of the Fly has the three outer petals ovate, entire, smooth, herbaceous, and spreading: the two inner linear and dark purple; the lip of the nectary oblong, dark purple above, and herbaceous underneath, with a blue fpot or band below the upper lobes. Bee Orchis has the three outer petals spreading, oblong, and purple, marked with three green nerves; the two inner lateral ones linear, villous, and green; the lip of the nectary large, roundish, purple, and like velvet, the lobes deflex, with a double variegated yellow, smooth, shining spot at the base. Spider Orchis is a lower plant; the lip of the nectary is of a less cheerful colour, without any of the yellow that decorates the Bee, and both helmet and wings are green: the three outer petals are oblong and spreading, the inner linear and shorter; the lip of the nectary is large,

Ee3

roundish,

y Ophrys insectifera arachnites Lin. Oph. aranifera Huds. Engl. Bot. 65. Vaill. t. 31. f. 15, 16. Ger. 212. 3.

roundish, entire, emarginate, convex, and appearing like velvet, dusky purple above, with a green edge, and a double spot at the base; beneath it is herbaceous. three beautiful plants are found among grass in a chalky soil, and form a succession from April to August; the Spider comes first in April and May, the Fly next in June, and last of all the Bee in July and

August.

I have been the more particular on this fingular tribe of plants, because, spurning culture, they are not liable to effential changes, or indeed to any that I know of except in colour: you must also search for them abroad, and confequently unite exercife with study, which is one of the principal advantages of Botany; for I cannot allow you to gather plants by proxy, fince you would thus lose half the pleasure of the pursuit, as well as the benefit: and why should you not have as much enjoyment in fearching for a beautiful plant, or finding an elegant flower, as the men have in looking for a hare, or shooting a partridge? I will only add, that should you be so happy Cypripe- as to meet with the Lady's Slipper2, you would be highly delighted with its fingular, large, hollow, inflated nectary, the form of which has given occasion to the name.

dium.

Haller

<sup>&</sup>lt;sup>2</sup> Cypripedium Calceolus Lin. Mill. fig. 242. Ger. 443. Sowerby's English Botany, t. 1 .- acaule & album are figured by Curtis.

Haller however observes, that it has more resemblance to a woodden shoe in form, and therefore is unworthy the title of Venus's Slipper, which Linnæus has bestowed upon it. Without entering into this important dispute, I will observe to you, that the root is fibrous; the stem about a foot high, and leafy; the two first leaves fmall, and keeping almost close to the stalk; the rest (from four to seven) ovate-lanced: one, or at most two flowers come out on the same stem, of which there are sometimes feveral from the fame root: the bracke is very large, as is also the germ: there are, but four petals to the flower, spreading out almost at right angles to each other, and often convolute; their colour is purple; of the two outer petals, one stands up above the nectary, the other hangs down behind it; the two inner petals stand out sideways, and are narrower: the flipper or lip of the nectary is yellow, spotted within, and marked longitudinally with ridges and fur-

# THE ORDER PENTANDRIA.

In the order *Pentandria* you will find Passissora the numerous and beautiful genus of *Passison-flower*. The flowers have three pistils, a five-leaved calyx, five petals to the corolla, a radiate crown for a nectary; and E e 4

the fruit is a berry on a pedicle. None of the species are European, but mostly natives either of New Spain, the Brafils, or the West Indian liles; so that they require the protection of the conservatory at least, if not of the stove, except one or two, which will stand abroad in a sheltered situation, with a little attention, in fevere weather. I shall select the species which you are most likely to meet with, rather than the rarest. Bine Passion-flower's, though a native of the Brasils, is seldom injured with us, except in very severe winters. Against a house it may be trained up to the height of forty feet, and throws out annually flender shoots, fifteen or sixteen feet long: the leaves are palmate or handed, composed of five smooth, entire, obtuse lobes, the middle one longest, the outer shortest, and often divided; they are petiolate; the petioles have two glands, and at their base is a stipule in form of a crescent, and a long clasper, by which the flender shoots support themselves: the flower comes out at the fame joint with the leaf, on a peduncle near three inches long; round the centre of it are two radiating crowns, the inner inclining towards the central column : the outer, which is longer, spreading flat upon

<sup>&</sup>lt;sup>a</sup> Peffiflora cærulea Lin. Mill. Illustr. Curt. Magaz. 28. and Plate 30 of this work. There is a splendid figure of it in Dr. Thornton's Illustration of the Sexual System.

the petals, and composed of innumerable threads, purple at bottom, but blue on the outside. On the top of the central column fits an oval germ, from whose base five awlshaped stamens spread out horizontally, and these are terminated by oblong, broad pendent anthers, which are easily moveable: from the fide of the germ arise three flender, purplish styles, diverging, and ending in obtuse stigmas: the flower continues but one day, but there is a constant succesfion from July till autumnal frosts stop them. The germ swells to a large, oval fruit, of the fize, shape, and colour of the Mogul Plum, inclosing a sweetish but difagreeable pulp, in which the oblong feeds are lodged.

Incarnate or trilobate Passion flower b is a native of North America, and though the first species known among us, is not so common as the Blue. It differs from the former in having only three lobes to the leaves, which are serrate or toothed like a saw; the side lobes are sometimes divided into two narrow segments: the petals of the corolla are white, with a double, purple fringe, star, or glory: the fruit is as large as a middling apple, and when ripe is of a pale

orange colour.

There is a fort, called Granadillac in the

b Paffiflora incarnata Lin. Mor. Hist. s. 1. 1. 1. 1. 9.
c Paffiflora maliformis Lin. Plum, amer. t. 82

West Indies, where the fruit is eaten. It has undivided, oblong leaves, hollowed next the petiole, which has two glands; the involucres are quite entire, as are also the leaves about the edge. The corolla is large with white petals, and a blue glory. The fruit is roundish, the size of a large apple,

and yellow when ripe.

Another fort, called Water Lemon in the West Indies, has an agreeable acid flavour in the pulp of the fruit, which quenches thirst, and is given there in fevers. It has undivided ovate leaves, quite entire about the edge; two-glanded petioles; and toothed involucres: the corolla is white with brownish red spots, and the glory or crown is violet: the fruit is of the fize and shape of a pullet's egg, and when ripe is vellow. But fince the rarer species may not readily fall under your cognizance, I restrain my defire of enlarging on fo remarkable and beautiful a genus; and pass on to a vulgar plant, which you will find in the last order Polyandria, and with that I will close our examination of this class, and my prate for the present.

d Passisson laurisolia Lin. Jacq hort. 2. t. 162. amer. pict. t. 216—P. alata is figured in Cuttis's Magaz. 66. and P. lunata is most elegantly figured by Mr. Sowerby, in a superb and splendid work, begun by J. E. Smith, M. D. under the title of Icones pictae Plantarum rariorum—Mr. Sowerby has given the flowers of several species, in a differtation on this genus in the Linmann Transactions.

# THE ORDER POLYANDRIA.

and the second section is the second section to

This is the common Arum, Wake-Robin, Arum, or Cuckow-pint , called alto vulgarly Lords and Ladies. Early in the spring it pushes up a one-leafed cowl-shaped spathe, under hedges and among buthes; if you open this spathe, you discover a spadix, naked on the upper part, covered with germs at the bottom, and with anthers in the middle. This is distinguished from the other species. which are many, by having no frem but that which bears the fructification, hastate leaves that are quite entire, and the spadix club-shaped. Though it has the trivial name from the black ipots upon the leaves. yet that is not a constant character, for oftentimes they are quite plain. As the plant advances, the spathe opens, and discovers the club, varying from yellowith green to fine purple or red; this gradually decays, and leaves a head of round red berries, which, as well as the rest of the plant, are very hot and biting. To this, with some others nearly allied to it, you would perhaps find it difficult to affign the proper class, unless, from the strange and unusual appearance of the fructification, you were

e Arum maculatum Lin. Curtis, Lond. II. 63. Mill. Illustr. Mill. ic. t. 52. f. 1. Blackw. 228. Fl. Dan. 305. Ger. 834. 1.

led to fearch for it in that now under confideration. These have not properly the stamens growing upon the style, but both are borne upon a receptacle lengthened out in manner of a style, and performing the same office as the pistil in the other genera. Linnæus observes that he might, and perhaps ought to have ranged such plants under other classes; but he was deterred by the difficulty of assigning the number of stamens to each pistil. Since he found a difficulty in removing them, though others have not, you and I, dear cousin, will leave them quietly in the place which he has assigned them.

The second of the least of the wife

# LETTER XXVIII.

# THE CLASS MONOECIA.

May the 15th, 1777.

INTE have hitherto, dear cousin, been VV conversant with such plants as bear perfect or complete flowers only, except in the class Syngenesia, wherein we found imperfect, and even neuter, floscules among the perfect ones. But in the twenty-first and twenty-fecond classes, which we are now to examine, you will never find any complete or perfect flowers; on the contrary, if they have stamens, there are no pistils, and if they have pistils, they are deficient in stamens. This is the common character of these two classes, and the only difference between them is, that in the class Monæcia, the staminiferous and pistilliferous flowers are found on the same individual plant; whereas in the class Diacia they are always on distinct plants of the same species. It is scarcely necessary to add, that in both, the flowers which produce stamens fall off without being followed by fruit or feed; and that the others, which have the germ, are fruitful.

The class Monæcia, which is the twenty-first in the system, has eleven orders, tak-

ing their titles and characters from the foregoing classes; eighty genera, and three hun-

dred and seventy species.

The third order, Triandria, contains feveral genera nearly allied to the Graffes in habit, leaves, and placentation, or having only a fingle lobe to the feed: they differ however in the culm or ftraw not being hollow, but filled with a spungy substance;

and in having no corolla.

Typha. Since Haller thinks there is a natural connexion between the Arum, with which I finished my last letter, and the Typha or Cat's-tail, let us begin our examination with this. Having three stamens, it belongs of course to the order Triandria, and having the air of the graffes, it ranges in the natural tribe of the Calamaria, just mentioned. The flowers of both kind, are borne on a cylindric Ament: the stammeous flowers furrounding the end of the stem; and those which have the piftuls growing in the same manner below them, and very close fet: there is no corolla to either: the first have an obscure, three-leaved calvx; in the fecond it confifts of pappous or villous hairs, and these have one feed, sitting on a capillary down or briftle: fuch are the generic characters. The greater, or broad-leaved Cat's-tail, otherwise called Reed-mace , is

know.

Typha latifolia Lin. Curt. Lond. III. 61. Mor. Hist. s. 8. t. 13 f. 1. Ger. 46. Park. 1204. I.

known by its fword shaped leaves, and by having the two aments approximating. It is a large plant, being about fix feet in height, with leaves three feet long and more, but not an inch wide; it is common in the water, on the banks of rivers, but especially in moats, ponds, and marshes. There is a smaller species, not so common, which has semi-cylindric leaves, and the two aments remote from each other; the stem of this is not above three feet high, and the leaves are much narrower, stiffer, and embrace the stem more.

Sparganium, or Bur-reed, approaches very Sparganear to Typha: but the flowers of each fort nium. are collected into a head, or roundish ament, those which have stamens above, and those which have pistils below, on the same stem, neither have any corolla; both have a three-leaved calyx; the pistilliferous flowers have a bisid stigma, and are followed by a single juiceless drupe, containing one seed. Erest or greater Bur-reed is common in the same situations with Typha, and sew plants exhibit more plainly the character of the class Monæcia. The stem is erect, and about three seet high; the leaves are erect and

<sup>8</sup> Typha angustifolia Lin. Curtis, Lond. III. 62.

ramofum. Ger. 45. 2. Mor. f. 2.

three-fided, but the upper one flat: the

stalk is generally branching.

Zea.

Mays, otherwise called Indian or Turkey Corni, is of the same tribe. The stamineons flowers are borne in loofe fpikes: their calyx is a two-flowered awuless glume: neither has the corolla any awn. The other flowers which have one pistil only, are in very close spikes, below the former. and are inclosed with leaves. The glume both of calyx and corolla is bivalved: the style is filiform, very long and pendulous: one feed follows each flower: the receptacle is oblong and hollowed, fo that the feeds are immerfed half way into it, forming a very dense spike. The West Indian Mays has a stalk ten or twelve feet high; long, broad leaves; and spikes from nine inches to a foot in length, formed of goldcoloured grains. That which is cultivated in Italy, Spain, and Portugal, has more flender stalks, not more than fix or feven feet high; the leaves narrower; the spikes shorter and more slender, with white grains. The North American Mays, which is the fame with what is cultivated in Germany. does not rife more than four feet in height: the leaves are still shorter and narrower; the spikes not more than four or five inches long, with yellow and white grains mixed: the colour of these however varies;

1 Zea Mays Lin. Blackw. 547.

indeed

indeed the three diffinctions are but varieties arising from foil and climate.

Carex, or Sedge, is a most numerous ge- Carez. nus of the same order, and the same natural tribe. The flowers of both forts are borne on an ament or catkin, and each flower has a one-leafed calyx, and no corolla; the pistilliferous flowers, which are generally in distinct aments below the others, have an inflated, three-toothed nectary, three stigmas, and a three-fided feed inclosed within the nectary. Some few species have only one spike; many have several spikes. with both forts of flowers in each; but more have the staminiferous and pistilliferous flowers in distinct spikes. These plants grow chiefly in marshes, bogs, ditches, wet woods, and the banks of brooks and rivers; they are the grais and fodder of fenny countries, and low swampy grounds k.

In this class, Monæcia, as well as in the next, you will find many trees. In the order Tetrandria—Birch, Alder, Box, Mulberry; in that of Polyandria—Oak, Cork, Evergreen Oak, Walnut, Hickery, Chefnut, Beech, Hornbeam, Hazel, Plane;—

Carex pendula Curtis III. 63. riparia IV. 60, acuta 61, gracilis 62.—dioica Fl. Dan. 369, capitata 372, arenaria 425, muricata 284, remota 370, canetcens 285, limoia 646, capillaris 168, panicea 443, vesicaria 647, hirta 379.—pauciflora Lights. 6. 2. incurva 24. 1.—Many of the species are figured in Leers's excellent Flora Herbornensis; in Engl. Bot. and in the second volume of the Linnæan Transactions, where there is an elaborate treatise on the British species by the learned Dr. Goodenough.

Betula.

and lastly in that of Monadelphia-all the species of Fir and Pine, Cedar, Larch, Arbor Vitæ, Cypress.

Alder is of the same genus with Birch: their common character is, that the flowers of both forts grow in aments or catkins, each separate from the other; that the calyx is one-leafed and trifid; that each calyx in the staminiferous ament includes three flowers, that have four-parted corollas; in the pistilliferous aments there are only two flowers in each calyx, without any corolla; but these are followed by seeds winged with a membrane on both fides, whereas the others drop from the tree, without leaving any mark behind them. In examining thefe, and the flowers in general of this and the following class, I must once for all inform you, that fince many of them are close set together in the same ament, you must carefully separate one flower from the rest, to avoid confusion. You must also look for them very early in the spring, since most of the forest and timber trees flower before the leaf-buds expand.

Common Birch 1 has ovate leaves, drawn to a very narrow point at the end, and ferrated, or sharply toothed round the edge. Linnæus distinguishes the Alder m by its

m Betula Alnus Lin. Duham. t. 15. Ger. 1477. 2. Evelyn's Silva by Hunter, p. 233.

branching

<sup>&</sup>lt;sup>1</sup> Betula alba Lin. Blackw. t. 240. Duham. t. 39. Ger. 1478. Evelyn's Silva by Hunter, p. 218.

branching peduncles: the feeds also are borne on a roundish ftrobile, rather than an ament; and the leaves are roundish, crenate or obtusely notched round the edge; they are of a dark green, with very prominent nerves underneath, and little spungy substances where they divide: the bark of the Alder is black, whereas that of Birch is white.

In Box both forts of flowers come forth Buxus. together in bunches, from the axils of the leaves or branches, and fit close to the stem: the staminiferous flowers have a three-leaved calyx, with two petals to the corolla, and the rudiment of a germ; the pistilliferous flowers have a four-leaved calyx, three petals to the corolla, three styles, and a three-celled capsule, terminated by three beaks, and having two seeds in each cell. Properly speaking, there is only one species of Box, varying a little in the shape of the leaves, and much in the size.

Mulberry bears the staminiferous flowers Morus. in an ament; the others in a separate roundish head, which afterwards becomes a compound berry, with one seed in each protuberance; the first have a four-parted calyx,
in the pistilliserous ones it is four-leaved,
and these have two styles; neither have
any corolla. White Mulberry, which is

<sup>&</sup>lt;sup>n</sup> Buxtus fempervirens *Lin.* Blackw. 196. Ger. 1410. Morus alba *Lin.* 

the fort commonly cultivated in France and Italy for feeding filk worms, has smooth leaves, obliquely heart-shaped, and white fruit. Black Mulberry P has rugged, heartshaped leaves: though cultivated for the fruit, yet the leaves are preferred to those of the other for feeding filk-worms, and are used for that purpose in Persia, from whence this tree originally came into the fouth of Europe. White Mulberry is a native of China. Of another species 4, paper is made in Japan, from the bark; this has palmate leaves, and hispid fruit. Fultick Wood r is also from a species of Mulberry: this has axillary thorns, and the leaves are oblong and more extended on one fide than the other. This grows in the islands of the West Indies, but in greatest plenty at Campeachy: the wood is imported into Europe from both places for the use of the dyers, but the tree is too tender to fupport our climate.

Quercus. In the order Polyandria the Oak leads the way. The staminiferous flowers hang on a loose ament or catkin, whilst the pistilliferous ones are sessible in a bud: the calyx of the former is mostly quinquesid, and the stamens are from sive to ten in number: in the latter the calyx is one-

P Morus nigra Lin.

<sup>4</sup> Morus papyrifera Lin. Seba mus. 1. t. 28. f. 3.

Morus tinctoria Lin. Sloan. Jam. 2. t. 158. f. 1.

leafed and quite entire, and there is one flyle split into five parts; but sometimes only into two, three, or four. The fruit, or acorn, is well known; it is an oval nut, covered with a tough shell, and immersed

at bottom into the calyx or cup.

We have two principal forts, or perhaps rather varieties, in England: one with the leaves on longer petioles, and the acorns feffile, or on very short peduncles; the other, having the leaves not so deeply, but more regularly sinuate, the sinuses being opposite; they have scarcely any petioles: on the contrary the acorns grow on very long peduncles, are larger, and come out sewer together. There are some other variations in this noble tree, which being less considerable, do not attract our notice as Botanists. Several species different from ours are sound in North America; and some in the southern countries of Europe.

Ilex or Evergreen Oak has oblong-ovate leaves, of a lucid green above, but hoary underneath, standing on long petioles, and continuing all the year; they vary much, some being quite entire, long and narrow; others broad, with the edges toothed and

Linnæus makes them one, under the title of Quercus Robur, and describes the species as having deciduous leaves, of an oblong form, but broader towards the upper part; the sinules acute, and the angles obtuse. Duham. t. 46—48. Evelyn's Silva by Hunter, p. 07. Ger. 1339. Fl. Rust. t. 10, 11, 12.

Ouercus Ilex. Lm. Ff3 fet

fet with prickles, almost like those of the Holly: the acorns are of the same shape with those of the Oak, but smaller. The grain-bearing Ilex", which yields the kermes or scarlet grain, has ovate leaves toothed on the edge, and the indentures armed with prickles as in the Holly; they are smooth on both fides: this is of fo small a growth, that it may be looked upon rather as a shrub than a tree. The Cork-tree v is a fort of Ilex, with a fungous bark full of clerts or chinks, which is the principal as well as most obvious difference: in the air, and form of the leaves, it much refembles the Evergreen Oak: the leaves however fall off in May, before the young ones come out, to that the Cork-trees are bare for a short time; which is not the case with the Common Ilex. Most of the trees in this genus are much reforted to by infects, many of which form different forts of galls; but here we are stepping out of our province:—we will return to it again, by taking the Walnut under consideration.

Juglans. This genus has the staminiferous flowers thick fet in oblong, cylindric catkins, under the lower leaves of the branches; they confift of scales with one flower to each; the corolla is fix-parted and the stamens are usually eighteen, but vary in number from twelve to twenty-four. The pistilliferous

Quercus Suber Lin. Blackw. 193.

flowers

<sup>\*</sup> Quercus coccifera Lin. ....

flowers come out close to the branches. above the others, at the base of a petiole, generally in pairs: these have a quadrifid calyx crowning the germ; a four-parted corolla; and two styles: the fruit is a drupe containing a nut, with a furrowed shell, within which is a four-lobed irregularlyfurrowed nucleus. Common Walnut " is diftinguished by having the component leaves oval, fmooth, fometimes a little toothed, and almost equal: there are many varieties in the fruit, and several distinct species in North America, one of which is the Hickery\*. All the species have pinnate leaves, with a different number of leaflets; ours has from five to nine, and the odd leaflet is rather the largest. Hickery has seven lance-shaped leaslets, toothed on the edge, and the odd one fessile.

Linnæus joins the Chefnut and Beech in Fagus. one genus, with this character: that the staminiferous flowers, which are in catkins, have a quinquesid, bell-shaped calyx, and about twelve stamens: that the pistilliferous slowers, which are produced from buds on the same tree, have a four-toothed calyx, three styles, and a muricate, sour-valved capsule, which before was the calyx, and contains two nuts. He observes that the staminiserous slowers in the Chesnut are

Ff4 disposed

Juglans regia Lin. Mill. Illustr. Hunt. Evel. Silva, p. 164.

<sup>\*</sup> Juglans alba Lin. Catesb. car. 1. 38.

disposed on a cylindric ament, whereas those of the Beech are in a ball. The catkins indeed of the former are very long, and the knots of flowers have near ten in each, and are distant from each other: the stamens are from five to eighteen, and have short filaments: the pistilliferous flowers are at the base of these, and are succeeded by two or three fruits close together; their; calyx has more frequently fix fegments. than four: the fruit varies in the number of kernels and pistils, but the most common number is fix; and the kernels are convex on one fide and flat on the other. The catkins of the Beech are roundish and loose. with few flowers; the stamens are eight in number on long filaments; and there are only two pittilliferous flowers together, and each of these is succeeded by a roundish nut, containing three or four hard threefided kernels, which are commonly called. Beech mast. The specific difference which Linnæus affigns to the Chefnut y and the Beech z, is taken from the leaves: which in the first are lance-shaped, sawed with the teeth ending in points, and naked or fmooth on the under furface; in the second ovate and obscurely toothed, or rather waving on the edge.

F Fagus fylvatica Lin. Evel. Silva by Hunter, p. 131.

y Fagus Castanea Lin. Mill. fig. pl. 84. Evel. Silva by Hunter, p. 153. Ger. 1442.

are ditposed in eatkins: both have a calyx consisting of one ciliate or fringed scale, and no corolla: the one has from eight to fourteen or sixteen stamens; the other has two germs, with two styles to each, and at the base of each scale of the ament or strobile lies a seed, which is an ovate nut. In the Common Hornbeam the scales of the strobiles are stat; and in the Hop-Hornbeam they are instated: such is the specific difference of these, which are the only known species. The leaves are wrinkled, marked with strong nerves, of an ovate form, and sharply toothed about the edge.

Hazel has the staminiferous flowers on a Corylus.

long cylindric catkin, with one flower to each scale, which is trifid; it has from six to ten stamens; generally eight: the pissilliferous flowers are remote from the others, sessile and inclosed in a bud; the calyx is two-leaved and torn: each flower has two very long, red styles; but you must observe that there are several slowers in the same bud, which you must therefore separate for examination: the fruit, as you know, is an ovate nut. As usual, neither of the slowers has any corolla. The Common Hazel nut and Filbert are supposed

<sup>&</sup>lt;sup>a</sup> Carpinus Betulus Lin. Evel. by Hunter, p. 158. Duh. t. 49. Ger. 1479.

b Carpinus Ostrya Lin. Mich. gen. t. 104 f. 1, 2. Corylus Avellaria Lin. Blackw. 293. Evel. Silva by Hunter; p. 213. Duham. t. 77. Ger. 1438. Engl. Bot. 723.

not to be specifically different, and the species is characterized by the stipules, which are ovate and end obtufely; whereas those of the Byzantine or Spanish nutd, which Linnæus gives as a diffinct species, are linear, and end acutely. There do not arrive at the dignity of trees, but are only Thrubs.

Platanus. The last tree I shall point out to you of this order is the Plane; which has the flowers of both forts in globular aments: the staminiferous flowers have a few very fmall scales for the calyxes, a corolla scarcely apparent, and anthers furrounding the filament; the pistilliferous flowers have many very small scales to the calyx; many petals to the corolla; subulate styles with recurved stigmas; and roundish seeds, terminated by a pointed style, and having a simple down adhering to their base. The two species of this tree, for there are no more, are well distinguished by their leaves, which in the Eastern or Asiatic Plane° are palmate; and in the Occidental or Virginian f, lobate. The first was introduced early to Rome, and was the favourite tree of the Romans at their villas. All thefe trees are included in a natural tribe called Amentaceæ by Linnæus, and Juliferæ by Haller and others;

d Corylus Colurna Lin. Seba mus. 1. t. 27. f. 2.

e Platanus orientalis Lin. Ger. 1489. Park. 1427. Platanus occidentalis Lin. Catesb. car. 1. t. 56. Duham. arb. t. 25. Park. theat. 1421.

their character is sufficiently obvious from their name, and what has been already faid in delivering the characters of the genera.

There remains still a fet of kindred trees, Pinus. of the order Monadelphia, and of a natural tribe, entitled Coniferæ or Cone-bearing. Of these the Pine genus is chief: its generic characters are, that the staminiferous flowers are disposed in racemes, having each of them a four-leaved calyx; no corolla, but abundance of stamens terminated by naked anthers; the pistilliferous flowers are on a cone; each scale or calyx has two flowers, without any corolla; one pistil; and a nut

furnished with a membranous wing.

The whole genus may be divided into the Pines, having two or more leaves from the tame sheathing base, and the Firs, having the leaves quite distinct at the base. Of the first division, the most known among us is the Scotch Pines, or, as it is vulgarly called, Scotch Fir: this has two leaves in a sheath; and the primordial ones solitary and smooth. It is by no means peculiar to Scotland, but is found all through Denmark, Norway, and Sweden, in Switzerland, and most other parts of Europe, and even in the West Indies. The Pineaster or wild Pine of Italy, the fouth of France and Switzerland, refemble this, but the branches are wider distant, and more hori-

zontal:

g Pinus sylvestris Lin. Mill. Illustr. Evel. Silva by Hunter, p. 274. Ger. 1356. 1.

zontal; the leaves are larger, thicker, and longer, grow straight, are of a darker green, and end obtufely; the cones are feven or eight inches long: the leaves of the Scotch Pine are broader, grayish, and twisted: the cones small, and of a light colour: the timber also is far preferable, yielding the best red or yellow deal. Linnæus, however, does not feem to have distinguished them. The Stone Pineh has also double leaves, and the primordial ones folitary, but fringed; they are of a glaucous hue: the cones are thick, roundish, and end obtusely; the scales are flat, and the nuts so large, that in the fouth of France and Italy they think it worth while to break them, and ferve the kernels up in defferts. Frankincense Pine has three leaves coming out of the same sheath, and cones as large as those of the Stone Pine, but more pointed, and with loofer scales, that open horizontally. and drop the feeds. The Cembra Pine k has five leaves in a sheath; they are smooth, of a light green, long, and narrow; the cones are about three inches long, with close scales, and large feeds easily broken. Weymouth Pine has also five leaves in every

h Pinus Pinea Lin. Blackw. 189. Duham. arb.

ham 2. t. 32. 1 all 2011 and and sooid event of Pinus Strobus Lin. Hunt. Evel. Silva, p. 27672

Pinus Strobus Lin. Hunt. Evel. Silva, p. 27678

fheath, long, and slender, but rugged on the edge: this tree grows remarkably straight and tall, and the bark is very smooth. In North America it is called White Pine, and is excellent for masts. The leaves of all these are linear and permanent; Linnaus calls this fort of leaf acerose.

Linnæus includes the Cedar of Lebanon and Larch in this genus; others separate them, because the leaves are fasciculate, or come out in clusters, spreading at the end like a painter's brush: this circumstance Linnæus gives for the specific distinction, adding, that in the former they are acute, and in the latter obtuse; this is the only difference he mentions: the leaves of the Larch however are deciduous, those of the Cedar permanent or evergreen; the character also of these two trees is totally different—the latter spreading its vast arms horizontally till the ends hang down with their own weight, and having a fastigiate or flat top—the former having the branches decreasing from the bottom upwards, and being therefore nearly pyramidal.

Of the Firs properly to called, the Pitch tree or Norway Fir and the Spruce, are

m Pinus Cedrus Lin. Trew. Ehr. t. 1. Edw. av.

o Pinus Picea Lin. Ger. 1363. Hunt. Evel. Silva, p. 278.

Pinus Abies Lin. Ger. 1354. Hunt. Ev. Silva, p. 278.

the most common. The first has the leaves emarginate, or notched at the end: this is the tree whence pitch is commonly extracted, and the wood of it is what we call white deal. The spruce has awl-shaped, pointed, smooth leaves, turned two different ways; the timber of this refembles the other, and, when cut into boards, is called by the same name. Silver Fir is so named from the whiteness of the leaves underneath; they are emarginate, and in shape much refemble those of the Yew: a great deal of turpentine is made from this. Balm of Gilead Firq has the leaves subemarginate, or but little notched at the end; they are dotted in a double line underneath. There are many varieties, especially of the Spruce: but it would lead us too far to notice them.

Cupreffus. I shall finish this knot of trees with the upright, the funereal Cypress, which has its staminiserous flowers collected into an ovate ament, with one-flowered scales, and four sessile anthers without filaments to each flower: the pissiliserous flowers are in a roundish cone, eight or ten in number, one to each scale; these have many truncated points, hollow at the top, which are perhaps the styles; under the scales of the cone lies an angled nut. Common Upright Cypress has imbricate leaves, with the leasing

<sup>r</sup> Cupressus sempervirens Lin. Blackw. 127.

branches

<sup>&</sup>lt;sup>9</sup> Pinus Balfamea Lin. Pluk. alm. 2. t. 121. f. i.

branches quadrangular: this takes naturally a close pyramidal form, and when large has the finest effect imaginable near buildings. Spreading Cypress is only a variety of this, but grows to a very large size, and surnishes the wood so famous for its durability, and resistance to insects. Deciduous Cypress has the leaves in two ranks, and spreading: it is a native of America, and grows to a vast size. But it is time to descend from trees to herbs, and thus put an end to this long letter.

The flinging Nettles' are to be found in Urtica. the order Tetrandria of this class; but such vulgar ill-humoured plants may forgive your passing them by, where you have so many interesting and even great personages to at-

tract your notice. Planto his to restaut

The immortal Amaranth however, have Amaraning superior elegance and beauty to boast, thus. will not thus be passed unnoticed. It is of the order Pentandria, and having no corolla, is ranged by some in the natural tribe of apetalous flowers. The same raceme or bunch bears incomplete flowers of both kinds, each of them having a three or five-leaved calyx; the one bearing three or five stamens, the other three styles, and a one-

· Cupressus disticha Lin. Cat. car. 1. t. 11.

celled

<sup>&</sup>lt;sup>t</sup> Urtica Lin.—pilulifera. Mill. Illustr. Engl. Bot. t. 148. Ger. 707. 1. Park. 440. 1.—urens Fl. Dan. 739. Ger. 707. Park. 440. 2.—dioica Fl. Dan. 746. Ger. 706. 2. Park. 441. 3.

celled capfule opening horizontally, with one feed only lodged in it. The species are numerous; one of the most known is the Amaranthus tricolor, cultivated for the beauty of its leaves, which are variegated with green, yellow, and red: this is one of those that have three stamens to the flowers, which grow in roundish heads, are axillary, and furround the stem; the leaves are broad lance-shaped. Amaranthus bicolor has only two colours in the leaves, an obscure purple and bright crimson: this refembles the other, but has lance-shaped pointed leaves. Prince's Feather has five Ramens to the flowers, which are produced in decompounded, cylindric, long pendulous racemes, of a bright purple, and two feet or more in length. Tree Amaranth refembles this, but is feven or eight feet high: the racemes are thicker, but not fo long. Bloody Amaranth w has also five stamens: the racemes are compound and erect, the fide ones very fpreading; the leaves are ovate-oblong: this has purple stalks and leaves; the racemes are short, and at the end of the stem there is a large cluster of them placed crosswife, with one upright in the middle; the flowers are bright purple at first, but grow darker. Thus I have

<sup>\*</sup> Amaranthus melancholicus Lin.

Amaranthus caudatus Lin.

<sup>\*</sup> Amaranthus fanguineus Lin. Mill. fig. 22.—cruentus Mart. cent. t. 6.

felected the most specious of this fine genusfor your examination: your gardener will furnish you with them from the hot-beds when he raises his annual flowers.

From the order Polyandria I shall pre-Sagittafent you with two wild herbs—Arrowhead and Burnet. The first has many staminiferous flowers, and a few with pistils
immediately below them: both have a threeleaved calyx, and a corolla of three petals:
the one has about twenty-four stamens: the
other many germs in a head, ending in
very short styles, terminated by acute permanent stigmas. Our common Arrow-head\*
is easily distinguished by its leaves shaped
like the head of an arrow, and pointed: it
grows in the water, has rounded white petals with purple claws, and bears an evident
affinity to Water plantain.

Burnet has incomplete flowers of both Poterium. forts in the same spike; those with stamens below the others: they have a four-leaved calyx, and a four-parted corolla: the lower ones have from thirty to forty stamens; the upper, two pistils, and a kind of berry formed from the tube of the corolla hardened. Common or smaller Burnet, is distinguished from the other species by being tunarmed or having no thorns; and the stems.

<sup>\*</sup> Sagittaria sagittifolia Lin. Fl. Dan. 172. Ger. 416. 2. Park. 1247. 2. Engl. Bot. t. 84.

For Poterium sanguisorba Lin. Curtis, Lond. II. 64. Ger. 1045. 1. Park. 582. 1. Fl. Rust. 1. 69.

being rather angular. This and the Great Burnet 2, though separated so widely in the artificial system, are evidently of the same natural genus: the calvx of the latter is two-leaved, and the number of stamens only four, and one pistil; both in the same flower: it is also a much larger plant, with not fo many pairs of leaflets: this grows in moist meadows: the other in dry, especially chalky pastures.

Ricinus, or Palma Christi, ranges in the Ricinus. order Monadelphia. The flowers have no corolla: fome are furnished with many stamens and these have a five-parted calyx; others have three bifid styles, with a threecelled capfule, containing one feed in each cell; in these the calyx is three-parted. Common Palma Christia has peltate, palmate leaves, toothed about the edge, of a glaucous hue underneath, and glands on the petioles. In the West Indies there are several others. varying from this, and from each other; which are not, however, generally supposed to be distinct species. They call them Agnus castus, or Oil-tree, and extract from them an oil for their lamps; this is the Caftor Oil, used in medicine. The common fort grows in Sicily, and the other warm parts of Europe.

The order Syngenefia of this class contains

<sup>&</sup>lt;sup>2</sup> Sanguisorba officinalis Lin. Fl. Dan. 97. Mor. Hist. s. 8. t. 18. f. 7. Ger. 1045.

<sup>\*</sup> Ricinus communis Lin. Mill. fig. 219.

a fet of plants that belong evidently to the fame natural tribe, entitled Cucurbitaceæ, or Gourd plants. They all agree in a one-leafed calyx, divided into five fegments; a fuperior, monopetalous corolla, divided also usually into five; three filaments; one style, generally trifid: and a pomum for a fruit.

Momordica is distinguished principally by Momorthe elastic bursting of the fruit, which in dicathe common fort is hispid: the stalks of this have no tendrils. From the property of throwing out the seeds with the juice, this plant has acquired the name of Spirt-

ing Cucumber b.

Gourd has the feeds of the fruit with a Cucurtumid margin. Long Gourd has the leaves bita. flightly angular, downy, two-glanded underneath at the base: the flowers white, on long peduncles, and reflex at the brim: the fruit crooked, yellow when ripe, and the rind hard and woody, so that it will contain liquids; whence it is called Bottle Gourd.

Pompion, corruptly called Pumkin<sup>d</sup>, is of this genus, and has lobate leaves with smooth fruit, which will grow to the fize of a peck.

The Squalbe, which is another species,

Momordica Elaterium Lin. Pl. 31. of this work.

Cucurbita lagenaria Lin. Mor. Hift. f. 1. t. 5. f. 3. Cucurbita Pepo Lin.

<sup>·</sup> Cucurbita Melopepo Line

has also lobate leaves, erect stems, and the fruit flatted and knotty.

Warted Gourd has likewise lobate leaves, and knobby fruit, covered with warts. These differ much in their form and fize.

Cucumis But the most known and cultivated of these fruits are the Melon and Cucumber, which belong to another genus, called Cucumis, having the seeds of the fruit sharp. Melon has the angles of the leaves rounded, and the fruit covered with little swellings: it varies much, as you know, in the form of the fruit. Cucumber has the angles of the leaves sharp, and the fruit oblong and rugged. All these having large slowers, with the parts very distinct, are proper to give you a just idea of this class: with these then I will sinish, and release you for the present.

<sup>&</sup>lt;sup>f</sup> Cucurbita verrucosa Lin.

<sup>&</sup>lt;sup>1</sup> This ruggedness is frequently lost by culture.

## LETTER XXIX.

#### THE CLASS DIOECIA.

Tune the 1st, 1777.

HE twenty-fecond class differs no otherwise from the otherwise from the preceding than in the disposition of the incomplete flowers. namely on different individuals of the same species; this is its effential character, and this gave occasion to its name—Diacia. There being no difficulty then in understanding this, which indeed has been repeated several times before, let us go on without further preface to the examination of fuch plants as are most likely to fall in our wayk.

Such is the Willow, which is of the fe- Salix. cond order-Diandria. Both staminiferous and pistilliferous flowers are produced in aments or catkins, on different trees; fo that you will have double trouble in examining the flowers of this class; for, when you have found one fort, you will have to look about, and perhaps have fome difficulty in finding the other. In fo delightful a study, however, you will not grudge a

k The genera in this class are fifty-five, and the species two hundred and nineteen.

little pains after having already taken fo much. The flowers of Willow have no corolla, and their calyx is nothing but the scales of the ament; there is a little honeyed gland in the centre of each staminiferous flower: you will eafily know the other aments, by the ovate germ in each little flower, gradually leffening to a pair of styles fearcely distinguishable from it, but by the two erect, bifid stigmas, with which they are terminated; this germ becomes a onecelled, two-valved capfule, containing many fmall feeds, crowned with a rough fimple down. There are anomalies in this genus; for one species has one, another has three. a third has five stamens, and a fourth has complete flowers. From more than thirty species I shall select the White Willow 1, which is a tree fo common in watery fituations: you will know it by the lanceshaped, acuminate leaves, toothed about the edges, pubefcent, or villous, on both furfaces, and having the lower ferratures glandulous: the leaves are very white underneath; and the catkins are short and thick: it will grow to be a large tree, when it is not headed. Several species are commonly cultivated in ofier-holts", but being al-

<sup>&</sup>lt;sup>1</sup> Salix alba Lin. Blackw, t. 327. Ger, 1389. I.

<sup>m</sup> Salix vitellina, amygdalina, purpurea, viminalis, &c. Lin.—Of thefe, S purpurea is figured in Curtis, Lond. n. 61. under the name of S. Monandria. For S. Triandria, fee n. 62.—S. Repens, Engl. Bot, 183.

ways kept down, in order to have a conflant fuccession of long, slender twigs, you will have little opportunity of examining their fructification. But one species being cultivated for its beauty, which fortunately depends upon the natural growth, you may study it at your leisure: this is the Weeping Willow, known at first sight-by its long, slender, pendulous branches; the leaves are smooth, narrow, and linear, tending to lance-shaped. Common Sallow has ovate leaves, wrinkled on the surface, which is villous above, and tomentose or nappy underneath, and slightly toothed or waved on the edges. There are several varieties of this vulgar species.

Misletoe is of the order Tetrandria; its Viscum. parasitic quality you are well acquainted with, and that alone makes it generally obvious to every body: it is however no part of its character. The genus is determined by a four-parted calyx, and an anther growing to each part, without a silament, in the staminiferous flowers; a four-leaved calyx sitting on the germ; no style; and a berry inclosing one heart-shaped seed in the others; neither have any corolla. Common or White Misses by lance-shaped

<sup>&</sup>lt;sup>n</sup> Salix babylonica Lin.

o Salix caprea Lin. Fl. Dan. 245. Ger. 1390. 3.

Ger. 1350. 1. Park. 1393. 1.

leaves ending obtufely, a dichotomous stalk, and axillary spikes of flowers.

In the next order *Pentandria*, we have Spinacia. Spinach, Hemp, and Hop. The first has a five-parted calyx in the staminiferous flowers, and a quadrifid or four-cleft one in the others: these have four-cleft styles, and one seed within the indurated calyx. Linnæus separates the garden fort from the Siberian, by the seeds being sessile, which in the latter are peduncled: of the former are several varieties: two remarkable ones, which perhaps may be distinct, the one having sagittate leaves, and prickly seeds;

the other rather ovate leaves, with smooth

Cannabis Hemp' has a five-parted calyx in the flowers which bear stamens, but in the piftilliferous ones it is one-leased, entire, and gaping on the side: these have two styles, and the feed is a bivalvular nut within the closed calyx. There is only one known species, and therefore until others are discovered, there is no occasion for any specific distinction.

Humulus Hop has a five-leaved calyx in the staminiferous flowers; in the others it is one-leafed, obliquely expanding, and en-

feeds. .

Spinacia oleracea Lin.

<sup>\*</sup> Spinacia fera Lin. Gmel. fib. 3. t. 16.

<sup>&</sup>lt;sup>t</sup> Humulus Lupulus Lin. Mill. Illustr. Engl. Bot. 427. Ger. 885. Park. 177.

tire; these have two styles, and one seed within a leafy calyx: many of them are collected together to form what we call the Hop. In the three last genera the flowers have no corolla.

The order Hexandria has the Tamus or Tamus. black Bryony, the flowers of which have a fix-parted calyx and no corolla; the pistilliferous flowers have a trifid style, and a three-celled berry below the flower, containing two feeds: our common species u

has heart-shaped undivided leaves.

The Poplars are in the order Octandria. Populus. The flowers of both forts are here borne on fimilar aments, confisting of scales torn on the edge, and each having one flower, without any petals, but a top-shaped nectary ending obliquely above in an ovate border; the pistilliferous flowers have a quadrifid stigma, and are succeeded by a two-celled capfule, containing many downy feeds. White Poplar v has roundish leaves indented on the edges into angles, and downy underneath. Great White Poplar, or Abele-tree. is a variety of this, with larger leaves, more divided, and of a darker green. Trembling Poplar, or Asp w, has leaves like the former

u Tamus Communis Lin. Mill. Illustr. Mor. Hist. f. 1. t. 1. f. 6. Ger. 871. Park. 178. 6. Engl. Bot.

v Populus alba Lin. Evel. Silva by Hunter, p. 201. Duham t. 36. Ger. 1486. 1. Park. 1410. 1.

w Populus tremula Lin. Blackw. 248. 2. 1487. 3. Park. 1411. 4.

in shape, but smooth on both sides; these being set on long petitoles that are flatted at the tip, tremble with the slightest breeze. Black Poplar \* has rhomboid leaves, pointed and toothed; they are smooth on both sides, of a light green; and the catkins are shorter than those of the two former. Carolina Poplar y has very large heart-shaped leaves, obtusely notched about the edges; and the shoots angled. Tacamahaca is a species of Poplar, with oblong ovate leaves, toothed about the edges, white underneath, with a scarcely visible down, and the veins forming a fine net-work: the stipules are remarkably resinous.

Mercurialis. Of the order Enneandria there is an herb, frequent under hedges and in woods, called Dog's Mercury \*: the flowers have a three-parted calyx, and no corolla; in fome there are nine or twelve stamens with globular, twin anthers; in others, on a distinct plant, two styles, and a two-grained, two celled capsule, containing one feed in each cell. The species here meant is distinguished

from the rest by its very simple unbranched

stem, and its rough leaves.

In the order Monadelphia you will find a Junipegenus of trees under the title of Juniper, rus. including not only the Juniper properly to called, which is rather a thrub than a tree, but also the Savin, and American or Sweet Cedars, &c. The staminiferous flowers in this genus are borne on an ament, the scales of which form the calyx of each flower having no corolla, but only three stamens: the pistilliferous flowers have a small, permanent, three-parted calyx, growing to the germ, which is below the flower; they have a corolla of three petals, three tiyles. and a three-feeded berry, with three tubercles of the unequal calyx on the lower part, and three little teeth at top from the remains of the petals. Common Juniper b has three spreading, pointed leaves, coming out together, that are longer than the berry. Savin ' has opposite, erect, decurrent leaves, with the oppositions boxed into each other along the branches; they are short and acute; this shrub spreads out much horizontally, rifing little in height. There are feveral species of Cedar natives of America. Bermudas Cedar d is that which is imported for cafing black lead in pencils, was for-

b Juniperus communis Lin. Mill. Illustr. Duham. t. 127. Ger. 1372. I. Park. 029. I.

<sup>&</sup>lt;sup>c</sup> Juniperus Sabina Lin. Blackw. 214.

d Juniperus bermudiana Lin. Herm. Lugdb. t. 347. merly

merly used for wainscoting rooms, and now for ships in the West Indies, the worms not attacking this kind of wood. The specific distinction is from the leaves: the lower ones being three-fold, the upper two fold o, decurrent, fubulate, spreading, and acute. Our plantations of shrubs have also the Red Virginia f, Carolina, and Barbadoes & Cedars; and there are others which are natives of the fouthern parts of Europe h.

Taxus. The baleful Yew is of the same order: the flowers have no corolla, nor, properly speaking, any calyx, unless we allow the three or four-leaved bud to be fuch: on fome trees they will be found to have many stamens, terminated by peltate, eight-cleft anthers; on others, to have an ovate, pointed germ, ending in an obtuse stigma without any style, the germ becoming a kind of berry, or rather succulent receptacle, with one feed in it, having the top naked: these flowers all come out from the axils of the leaves, which are linear, end in a sharp point, and are ranged in a double row close together along the mid-rib; the

<sup>.</sup> Miller fays fourfold and imbricate.

berry is red, and mawkishly sweet—not poisonous, though the leaves certainly are so.

I will now finish our examination of this Ruscus. class, and close this letter, with the fingular genus of Ruscus, the flowers of which have a fix-leaved calyx, no corolla, but an ovate inflated nectary, perforated at top, in the centre of the flower; the staminiferous flowers have no filaments, but only three anthers, fitting on the top of the nectary. and united at the base, whence this genus is of the order Syngenefia: the pistilliferous flowers have one style, and a germ hid within the nectary, which becomes a globofe three-celled berry, containing two globose feeds. The common species, which we call Butcher's Broom, or Knee Holly k, bears its flowers in the middle of the leaves, on their upper furface: these are of the shape and fize of myrtle leaves, but stiffer, and end in prickly points; the berries are red, and almost as large as cherries: in another species the flowers are produced on the under furface of the leaves: in a third " they are produced also underneath, but are protected by a leaflet, whereas in the other species they are naked: a fourth n flowers

from the margin of the leaves: and the Alexandrian Laurelo, which is a species of Ru/cus, from long racemes at the ends of the branches: the flowers of this are complete, and therefore the plant ought not to be found in this class; but fince it is evidently of this genus naturally, Linnæus has left it with its own family, choosing rather to violate the laws of his own arbitrary fyftem than those of nature. The stalks of this are flender and pliable; the leaves are rounded at the base, but end in acute points; they are smooth, and of a very lucid green: the flowers are of an herbaceous yellow colour, and are succeeded by berries like those of our Butcher's broom, but smaller. With this beautiful evergreen I leave you, dear cousin, till the next letter.

Ruscus racemosus Lin. Mor. Hist. s. 13. t. 5. f. 14.

## LETTER XXX.

## THE CLASS POLYGAMIA.

June the 14th, 1777.

fin, who think the twenty-third class—Polygamia, might have been spared, and the plants comprized in it pranged in the other classes, according to the number, situation, proportion, &c. of the stamens. But let us take things as we find them, without inquiring too deeply into the merits of what, after all, is of no great importance. The essence of this class consists in having complete slowers, accompanied by one or both sorts of incomplete ones, either on the same or different individuals. The latter circumstance surnishes the character of the three orders.

complete and incomplete flowers always on the same plant, is hence entitled *Monæcia*. You may perhaps remember, that some of the Grasses were said to be of this order q: here also are the *Plantain-tree* and *Banana* r: *Valantia* or *Crosswort*, which you Valantia.

The first order of this class having the

P Genera 34, species 224.

<sup>4</sup> See letter XIII.

Musa paradiasiaca & sapientum Lin. Trew. Ehr. t. 18-23.

may find in hedges and bushy places, and will evidently perceive to be of a natural tribe's you have met with before: there is usually one complete flower in this genus, accompanied on each fide with an incomplete staminiferous one; the former has the corolla four-parted, four stamens, a bisid style, and one feed; the latter have the corolla trifid in fome species, quadrifid in others; three stamens in some, four in others, and an obscure pistil; none of the flowers have any calyx: frequently these plants produce incomplete flowers only, and therefore no feed; owing, I prefume, to their running fo much at the root. Our wild species t is one of those which have the incomplete flowers quadrifid, and it has two leaves to each peduncle, which supports about eight flowers, with yellow corollas; there are four leaves to each whorl, and they, with the whole plant, are covered with foft hairs.

Parieta-

Pellitory of the Wall has two complete flowers, with one pistilliferous flower between them, within a fix-leaved involucre; they have a four-cleft calyx, no corolla, one style, and one feed: the complete flowers are distinguished by having four stamens; the other has none. Our common spe-

\* Stellatæ: see letter XV.

<sup>&</sup>lt;sup>t</sup> Valantia Cruciata Lin. Blackw. t. 76. Mor. Hist. f. 9. t. 21. f. 1. Ger. 1123. 1.—Galium Cruciata. Engl. Bot. t, 143.

cies has broad lance-shaped leaves, dichotomous or forked peduncles, and two-leaved calyxes: the pistilliferous flowers are qua-

drangular and pyramidal.

Atriplex, or Orach, has fuch affinity with Atriplex. Chenopodium or Goofefoot, that, as Linnæus observes, if Orache had only complete flowers it would be a Goofefoot; and if this had pistilliferous flowers, it would be an Orache. Most of these are common weeds on dunghills, or on the fea-coast.

Acer, or Maple, is a tree in which you may Acer. examine the character of the class and order at your ease. The flowers are produced in bunches; the lower ones complete, and those which are towards the end staminiferous: they have a quinquefid calyx, a corolla of five petals; the complete flowers have besides all this one pistil, and two or three capsules, joined at the base, flat, each terminating in a large, membranaceous wing and containing one feed. The Great Maple, commonly called Sycamore, has five-lobed leaves unequally ferrate, and the flowers in large racemes. Common Maple w has lobed leaves, obtufe, and emarginate; generally

they are divided half way into three lobes. the fide ones obtufely femi-bifid, the middle one semi-trifid; the upper leaves rather cut into five lobes: the bunches of flowers are fmaller. This tree grows much in hedges.

Mimosa. The famous Mimosa or Sensitive belongs to this first order of the class Polygamia. The flowers have a five-toothed calyx, a five-cleft corolla, and five or more stamens: the complete flowers have also one pistil, and a legume for a feed-vessel. This genus is very numerous, but all the species are not endued with the fensitive quality. That which is most common in the islands of the West Indies, and in our stoves \*, has the stems armed with short recurved spines; pinnate leaves composed of four or five pairs of leaflets, whose base joins at a point where they are inferted into the petiole, fpreading upwards like the fingers of the hand; the flowers come out from the axils on short peduncles, in fmall globular heads, the corollas are yellow; they are fucceeded by fhort, flat jointed pods, with two or three orbicular, bordered, compressed seeds in each. Some species move much more readily than others; some drop the leaslets only, and others drop the petioles of the whole leaf also. The true Egyptian Acacia, and many other Acacias, having the same characters, are included in this genus: they

<sup>\*</sup> Mimosa pudica Lin. Comm. Hort. 1. t. 29.

y Mimofa nilotica Lin.

are too tender to flower much in our climate.

Three thorned Acacia' is of another ge-Gleditha nus, and indeed of another order-Diacia: for it has the staminiferous flowers in a long, compact, cylindric ament, with fome complete ones generally at the end of it; and, on a distinct plant, pistilliferous flowers on loofe aments. The complete flowers have a quadrifid calyx, a four-petalled corolla, fix stamens, one pistil, and a legume: the staminiferous flowers have a three-leaved calyx, a corolla of three pea tals, and fix stamens: and the pistilliferous flowers have a five-leaved calyx, a fivepetalled corolla, one pistil, and a legume. The common species is distinguished from the other a by its large thorns, which have generally two finaller ones, coming out from the fide: they are axillary, and are often produced in clusters at the knots of the stem; the leaves are pinnate, and have ten pairs of small leastets. In America, its native country, this tree is called Honey Locust.

The Ash-tree is also of this second order: Fraxinus having on some trees complete flowers, on other pistilliserous ones, each frequently accompanied by the others; they have either a four-parted calyx or none, a corolla

<sup>\*</sup> Gleditsia triacanthos Lin. Duham, 1. t. 105. Hort. Angl. t. 21:

dedittia inermis Lin. Mill. fig. pl. 3.

of four petals or none, and one pistil: the complete flowers have also two stamens, and one lance-shaped seed. Common A/b; has pinnate leaves, with five pairs of leaslets, slightly serrate on the edge; the flowers have neither calyx nor corolla, and are produced in loose bunches from the sides of the branches. Flowering A/b has the leaslets serrate; the flowers are surnished both with calyx and corolla; and are in large loose bunches at the ends of the branches. The American or Carolina A/b has the leaslets quite entire, and the petioles round.

Ficus.

Of the third order-Triacia-we have the Fig, which though it bears flowers that are visible, yet conceals them within the fruit, and therefore may lead us well enough to the class Cryptogamia. What we call the fruit of the Fig, Linnæus names the receptacle, or common calyx of the flowers; he describes it as being top-shaped, fleshy, converging, closed at the broad end with feveral scales, and having the inside covered with little flowers, complete and incomplete: fometimes in the fame fruit, and fometimes on different trees: the staminiferous flowers have a three-parted calyx, and three stamens; the pistilliferous flowers have a five-parted calyx, one pistil,

and one roundish, flatted seed: neither of them have any corolla. Our common or eatable Fige is distinguished by its palmate leaves: the different fruits are but varieties arising from the same seed. The history and occonomy of this singular tree, as related by naturalists and travellers, will be an agreeable relaxation to you amidst our dry botanical disquisitions.

\* Ficus Carica Lin. Mill. Illustr.

# LETTÉR XXXI.

OF THE NECTARIUM OR NECTARY.

June the 21st, 1777.

AVING now gone through all the classes of conspicuous flowers, we should regularly proceed to the last class of the system, in which they are inconspicuous; but having kept on a straight course for a long time, we will now turn out of it, and take a view of the different appearances which the nectary puts on, in the several genera of plants wherein it is found.

Several of these have been cursorily mentioned as characters of the genus; and we have even hinted at the general use of the nectary; but we shall now go farther, and say, that though this part of the flower has not hitherto been observed in two hundred generas, yet that in all probability it exists in all, if not as a distinct visible part, as a gland or pore however, or a set of glands or pores, exuding that viscid sweet juice, so useful secondarily for the nourishment of a great variety of insects, and at the same time doubtless primarily necessary to the fructification of the plant itself. For you

See Letters IV. and XVII. Besides the Grasses.

Will

will observe in monopetalous tubular corollas, that though they have no visible nectary, yet there is a nectareous juice fecreted into their tubeh, which is therefore probably provided with glands for this purpose, too minute to be seen with the naked eye, but which an accurate inspection with glasses might perhaps detect. Polypetalous flowers with open calyxes, having no tube, or basin, for the reception of the nectareous juice, have in general a body destined to prepare and contain it, in order that it may be distributed to the surrounding parts of fructification, as it is wanted. In the compound and umbellate tribes of plants indeed no nectaries have been remarked; but then you remember, that the whole flower in both of them is fo small, that it is no wonder if a part, so minute as the nectary frequently is in larger flowers, should escape our observation in these: we may presume however, that they abound in nectareous juice, fince we observe that insects are particularly fond of these tribes. No genus of the class Icosandria has any distinct nectary: but then the calyx is one-leafed, and forms a commodious basin for the reception of the nectareous juice, which is frequently very discernible in it. The verticillate tribe also is not mentioned by Linnæus as being fur-

Didynamia Gymnospermia Lin.

h As particularly in the Honeyfuckle and Aloe,

nished with visible nectaries; nor are they perhaps immediately necessary here, because the corolla is monopetalous, and the monophyllous calyx forms a permanent tube: many genera however of this order have a gland in the bottom of the calyx, surrounding the base of the germ; this is large in the Bugle, and sufficiently visible in the Dead Nettle.

No appearance of the nectary is more common than this of glands. You have already feen k that they are confiderable in feveral genera of the cruciform tribe; that they have furnished us with generic characters: and that they are even the cause of the classical character itself. It has been just mentioned that they are found in the verticillate or labiate tribe: and many genera, dispersed in various parts of the system, have this glandular nectary. Thus Plukenetia (1080) has four glands at the base of the filaments, as in the class Tetradynamia. Cercis (510) has a style-form gland under the germ. Lathraa (743) and Orobanche (779) have a gland at the base of the germ. Cassyta (505) has three glands; Echites (299), and Tabernamontana (301), have five; Hernandia (1049) has

Letter XXIII.

<sup>&</sup>lt;sup>1</sup> See Letters II. IV. and V. compared with Letter XXIII.

m The figures refer to the number of the genus in Linnæus's genera and systema.

fix or four, furrounding the germ; and Grielum (1235) has a fet of oblong glands, round the germ uniting into a little crown. Malpighia (572) has two glands at the bottom and on the outside of each leaf of the calyx; in Banisteria (573) the case is the fame, except that one foliole of the calyx has no glands, and therefore the whole number is eight; whereas in the other it is ten. Reseda (608) has a gland arising from the receptacle between the stamens and the upper petal: and Croton (1083) has five of them, fixed to the receptacle. Astronium (1111) has five glands in the disk of the flower, Cucurbita (1091), or the gourd genus, has a fingle, triangular, concave gland in the centre of the flower; and in the Salix (1098), or Willow, the fituation is the fame, but the form of it is cylindric.

Another very usual form of the nectary is scales, which are in truth but flatted glands. Monnieria (850), and Vicia (873), or the Vetch genus, have one scale only, at the base of the germ. Cuscuta (170), or Dodder, has four scales, at the base of the stamens. But many have five scales: as Parnassian (384): at the base of the silaments in Schrebera (319), Quassian (529), and Melassoma (544); between the stamens in Iresine (1113); at the base of the germ, in Crassula (392), Cotyledon (578,) and Se-

dum (579); furrounding the receptacle in Samyda (543); or at the base of the petals. in Erythoxylon (575), Ranunculus° (699), Grewia (1026), and Kiggelaria (1128). Amaryllis (406), and Leontice (423), have fix scales; without the base of the filaments. in the first, and inserted into the base of the

petals in the fecond.

Not unfrequently does the nectary appear in the shape of valves, which are generally five in number; in Plumbago (213) placed at the bottom of the corolla, and inclosing the germ; furrounding the germ in Achyranthes (288); and covering the receptacle in Campanula (218) and Roella (219). Afphodel (421) has fix of these valves, inserted into the base of the corolla, and forming a complete arch over the germ; a filament fpringing from each of them p.

In Erythronium (414) there are two callous tubercles at the base of each inner petal; in the Laurus (503) genus q, three tubercles round the germ; and two round glands, on a short stalk, near the base of each filament of the inner rank. In some species of Iris there are three dots at the base and on the outside of the corolla; in Tamus (1119) an oblong dot grows to the infide of each division of the calyx; and in another genus, Swertia (321), are ten of

<sup>·</sup> Plate 34. f. 4. P Plate 34. f. 7. See Letter XIX, Puncta.

these dots; two at the base of each division of the corolla, surrounded with bristles. In the Hyacinth' (427) there are three pores at the top of the germ: and in both the genera of Fritillaria (411), and Uvularia (412), there is an excavation at the base of each petal: in the Crown Imperial this is considerable, and generally exhibits a large drop of nectareous juice. Mercurialis (1125) has two subulate acumens or sharp points, one on each side of the germ; and Vallisneria (1097) has a cuspis on each petal.

You remember the beautiful appearance that the nectary made in some species of Iris as a longitudinal villous line upon the petals: in the Lily (410) it is a pipe or tubulous line along the middle of each petal: and in Frankenia (445) it is a channel run-

ning along the claw.

In some genera the nectary takes the exact form of petals, and was always confounded with them until Linnæus pointed out the difference; this is the case with several plants of the first class w, and with Lecythis (664) in the thirteenth; in all these it is of one petal only; in Galanthus (401), or, Snowdrop, it consists of three parallel,

W Letter XI.

Our wild Hyacinth (H. non scriptus) has not these pores, or at least they are not visible to the naked eye.

\* See Plate 34. f. 6. \* Letter XXIX.

v Letter XIV. See Pl. 34. f. 5.

notched, obtuse, petal-like leastlets, forming a cylinder about half the length of the corolla. Illicium (611) has feveral awl-shaped folioles of the same length with the petals themfelves. Cardiospermum (498) has a fourpetalled nectary inclosing the germ; and in Hartogia (273), Sauvagefia (286), and Helicteres (1025), it is made up of five petals. Andrachns (1095) has five semi-bifid her baceous folioles, less than the petals, and placed between them. All the Graffes, Rice (448), and Mays (1042), agree in having a nectary of two minute, oblong leaflets. Swietenia (521), Melia (527), and Melianthus (795), have a one-leafed nectary, with a many-toothed mouth in the two first, and in the last within the lowest division of the calyx, to which it grows. In Musa (1141) also, the nectary is one boatshaped leaf, compressed, pointed, and inferted within the bosom of the petal. Ten converging leaflets, inclosing the germ, form the nectary of Zygophyllum (530); each leaflet being fixed to the base of each filament. Dalechampia (1081) has a broad nectary, composed of many ovate, flat plates in feveral rows.

I have mentioned before, that in tubulous corollas the nectareous juice is secreted into the tube: in many genera there is a horn or spur at the back of the flower, which answers this purpose of a recipient. Several plants have occurred in the course of our examinations with a nectary of this form; as Tropæolum (466), Lark/pur \* (681), Aconitey (682), Columbine (684), Antirrhinum (750), Fumitory (849), Violet (1007), Impatiens (1008), and Orchis (1009): to these we may add Pinguicula (30), or Butterwort, Utricularia (31), and Valerian (44.) In some species of Antirrhinum the horn is blunted, and becomes rather a bag; which is also its shape in the Satyrium genus (1010). The genera of this tribe are remarkable for their nectaries; in Ophrys (1011) it hangs down from the corolla, longer than the petals, and is keeled at the back part; in Serapias (1012) it is of the fame length with the petals, ovate, gibbous below, and with an ovate lip; in Limodorum (1013) it is of the same length with the petals, of one leaf, concave, standing on a pedicle, and within the lowest petal; in Arethula (1014) it is of one leaf, tubulous at the bottom of the ringent corolla, and connate with it; in Cypripedium (1015), or Ladies-Slipper, as you have feen before z, it is very large and inflated; and in Epidendrum (1016) it is tubulous at the base, turbinate, or top-shaped, with an oblique bifid mouth. Thus you observe that all the genera of this tribe have fingular nectaries: whereas in the three classes with

2 Letter XXVII.

<sup>\*</sup> Plate 34. f. 2. 4 y Plate 34. f. r.

conjoined filaments scarcely any are to be found. The numerous genus of Carex (1046), or Sedge, has an inflated, permanent nectary, contracting above, and toothed at top, where it gapes, but continues to invest the seed; in Ruscus (1139) also it is inflated and open at top, it is ovate, erect,

and of the same size with the calyx.

In many genera the nectary takes the form of fome well-known utenfil or other thing. Thus in Staphylaa (374), Tinus (504), Winterana (598), and Urtica (1054), or Nettle, it is Urceolate or Pitcher-shaped. In Narcissus (403), and Pancratium (404), it is Funnel-schaped. In Epimedium (148) it is Cyathiform or Goblet-shaped. In Byttneria (268), Theobroma (900), or Chocolate, Ayenia (1020), and Kleinhovia (1024), it is Bell-shaped. In Cissampelos (1138) it is Wheel-shaped: and in Epidendrum (1016), Poplar (1123), and Gleditsia (1150), it is turbinate, or shaped like a boy's top, narrow at bottom, and spreading out above. The most beautiful of these nectaries is the Crown-shaped: in Diosma this is placed on the germ; in Olax (45), Hamamelis (169), Nerium (297) or Oleander, Periploca (303). Silene (567), and Cherleria (570), it terminates the tube of the corolla: but in the Passion-flower (1021) it is a triple crown or

and in Diadelphia three. b See Plate 14. f. 2.

glory, the outer one longest, surrounding

the style c.

In Garidella (571), Nigella (685), and Hellebore<sup>d</sup> (702), the nectaries are bilabiate; the first has five, the second has eight, and the third has an uncertain number. Trollius (700) has nine linear, slat, bent bodies, perforated at the base, on the inside; and Isopyrum (701) has sive equal, tubulous, short nectaries, with a trilobate mouth, inserted into the receptacle, within the petals.

In Arum (1028) the nectaries refemble the filaments of stamens, only that they thicken at bottom; they come out in two rows from the middle of the spadix. In Peganum (601) the filaments themselves are dilated into nectaries at the base. In Fevillea (1118) they consist of sive compressed bent threads, placed alternately with the stamens. In Trichilia (528) the nectary is cylindric, and tubulous, formed out of the ten filaments, shorter than the petals, and with a five-toothed mouth.

You have observed that many nectaries already mentioned have an intimate connexion with the germ; it is a situation so common with this part of the slower, that some persons have suspected the sole or principal use of it to be to supply and softer the germ. Accordingly there are several other

e See Plate 30. Plate 34. f. 8. genera,

genera, in which it is thus placed. In Mirabilis (242), or Marvel of Peru, it is globose, permanent, and incloses the germ: in Cissus (147), Celosia (289), Limeum (463), and Phyllanthus (1050), it is a ring furrounding the germ: in Cynanchum (304) it is cylindric, with a five-toothed mouth; in Apocynum (305), Asclepias (306), and Stapelia (307), it is made up of five bodies, which in the fecond and third entirely conceal the stamens and pistils, and in the third forms a double star: all of them about the germ. In Gualtheria (551) it is made up of ten short, awl-shaped, erect bodies, furrounding the germ, between the Ramens. when the sold is sold I have been the

It must not be dissembled, however, that whatever use these bodies may be of to the germ, when they adhere to it, or are nearit; they are frequently found on other parts; of the fructification. Many instances of this have already occurred, and to these we may add, that they are found on the petals in Bromelia (395), growing to each of the three, above the base; in Berberis (442), or the Barberry, in two roundish orangecoloured bodies at the base of each; in Hermannia (828), each petal having a little mem brane, forming all together a cowled tube; in Hydrophyllum (204), and Reaumuria (686), in laminæ or plates growing to them; in Myosurus (394), being five awlshaped bodies. The nectary is found on the

the calyx in Tropæolum mentioned before, in Monotropa (536), in some species of Biscutella (808, and in Malpighia, mentioned also before among those which have glandular nectaries. This part is a globose gland on the exterior tip of the anthers in the Adenanthera (526), at the base of them in Ambrosinia (1238): and on the filaments in form of glands in Dictamnus (522), in form of scales in Zygophyllum (530), placed horizontally on the real filaments in Commelina (62); and in Plumbago, Campanula, and Roella, mentioned before. And lastly, the nectaries are not unfrequently placed on the receptacle; as in Lathræa (743), Clutia (1140), Melianthus (795), and some others: but these are so close to the germ, which takes its rife from the same base, that they may very well be supposed to be placed there for its use.

But what shall we say when we find the nectary in the incomplete stamniferous flowers, which have no germ; as in Willow (1098), Astronium (1111), Iresine (1113), Fevillea (1118), Poplar (1123), Rhodiola (1124), Kiggelaria (1128), Cissampelos (1138), Ruscus (1139), Clutia (1140), and Ophioxylon (1142). In all these cases it certainly cannot be of any immediate use to the germ, which is not only on a distinct slower but on a different plant: this however being the most important part of the vegetable, since it is destined by nature

ture to produce a new one of the same kind; and all the other parts of the flower being in some measure subservient to this, what-soever is immediately useful to these may fairly be said to be mediately serviceable to the germ.

But let us return to our history of facts, and finish this dry discussion, which I should not have troubled you with, if I could have directed you to any author where you might find the different forms and situations of the

nectary registered in one view .

Hitherto you have observed that this beautiful part of the flower is generally single, though in many cases formed of several portions: in some genera however it is double. Thus in Krameria (161), there are two nectaries, one above another; in Stapelia, as you have already seen, a double star, both flat and quinquesid, the lower with linear divisions torn at the end, surrounding the stamens and germs, the upper with acute entire divisions covering them: something of the same kind is observable also in Asceptias, the very singular structure of whose slowers is particularly deserving of your attention. Paullinia (497) also, and Sapindus (499), have two nectaries, very different from each other; the

When I writ this letter, I entirely forgot that there was a differtation on the same subject printed in the 6th volume of the Amænitates Academica. The learned reader may compare that treatise with this.

one confisting of four petals inserted into the claws of the real petals, the other of four glands at their bases. I may here obferve, that though the general use of the nectary, as the name implies, be to pour out the nectareous juice; yet it does not feem that all the bodies to which Linnæus has given the name ferve that purpose: fuch may probably be the case in one of these nectaries, of the genera before us, and perhaps of others, where this part is double. Lastly, Clutia (1140) has two sets of nectaries, one within the other; the outer of five three-parted, oblong bodies, placed in a ring within the petals, and of the fame length with their claws; the inner of five little glands, which are certainly milliferous at top: it is observable that in the piftilliferous flowers of this genus there are no glands or inner nectaries, and the outer ones are of the same size, and in the same situation, but differ in form, being roundish and didymous, or twinned.

Concerning the form and variations in the other parts of the fructification, which furnish the generic character of vegetables, enough is to be found in the elementary books f: of the leaves also, together with those other parts and circumstances, furnishing characters for the differences of about ten thousand one hundred species, which

Lee's Introduction; Rose's Elements of Botany,

is the whole number of plants at present arrangeds, there is no want of instruction in the same authors, translated from Linnæus's original works. I shall only remark to you therefore, that a more minute attention and accurate observation of vegetables, discovered to Linnæus parts that former botanists had passed by unnoticed; and that his fuperior fagacity and genius enabled him to make a much more extensive use of such as were already known. The parts I now callude to, are what he calls Fulcra, props or supports of the plant. Among these the arms or weapons, that is, thorns and prickles; claspers or tendrils; some forts of pube/cence; and perhaps glands, in some few species had been noticed; but in a manner very loose and imperfect: but the flipule, which is a scale at the base of the petioles; and the bracte, which is a scale or small leaf next the flower, had not been so much as named; nor had any one thought of using these seven important though minute parts for distinguishing the species, a business to which they are so well adapted, both by their constancy and abundant variety. Is not be brone of as ...

He has also taken in other circumstances very happily, besides the mere form, to surnish specific differences, and for other pur-

In the 14th edition of Systema Vegetabilium.— To these however a considerable number has been since added, from the South-sea islands, and other places.

poses; fuch as the mode and degree of ramification in leaves and branches, the intorfion, or manner of turning or bending in the stems; the gemmation, or various con-Aruction of the buds; the foliation, or different folding of the leaves before they are expanded; the inflorescence, or manner in which flowers are connected to the plant by their peduncles: all these, together with some others, which I have passed over, will occasionally furnish you with marks to distinguish plants from each other, even more certain in some cases than the form itself, and therefore highly worthy of your attention; but I have already trespassed on that too long, and will leave you to your leifure and more important concerns.

Ii3 LET-

#### LETTER XXXII.

#### THE CLASS CRYPTOGAMIA.

October the 4th, 1777.

HAVE at length found time, dear coufin, to fend you my last letter on the subject of Botany. I have not hastened it, because you have found full employment during the summer, either in examining such plants as had escaped you before, or in searching for their nectaries and other more minute parts. You have also by this time discovered that the study or amusement which you nave taken up, is not the

affair of a fingle feafon.

As to the last and lowest class of vegetables—Cryptogamia, I shall at present touch it very slightly, because, though sull of beauties, when examined with that attention which such small bodies require, it is much too difficult for our young cousin, and will probably be uninterresting even to you, unless you have already imbibed a greater passion for Botany than I wish you to have. The objects also of this class must be searched for in places, and at a season, by no means agreeable to your delicacy; and I will not have you risk your health, the most precious gift of heaven, even in pursuit

pursuit of the most delightful knowledge. Gentle exercise, such as a proper attention to the study of nature will induce you to take, accompanied with that cheerfulness, regularity, and temperance, for which you are so conspicuous, is your best security for a continuance of this blessing; and that you may enjoy it uninterrupted to a period yet distant, my good wishes shall not be wanting.

You are already acquainted with the meaning of the name Cryptogamia, and the character of the class h: you are also mistress of the four orders into which it is divided, together with their characters, such as they are i. I have only therefore to present you with a few of the most obvious species in each order, wherein the generic and specific characters are the least incon-

fpicuous.

The number of genera in this class are fifty-one, of species eight hundred and fifty-eight.

### FERNS.

The plants of the first order—the Ferns, are as large, and oftentimes as specious, as those of the foregoing classes; it is apparent also to the naked eye, that there is a fructification, though the parts of it are not

h See page 105.

I i 4

See page 114, &c.

diftin-

Equise-THEO.

distinguishable. The general face of this, as it appears to the microscope, has been

already describedk.

In general the fructification in this order of Ferns is on the back of the leaves; that however is not universal. For instance, in the genus Equisetum, or Horsetail, it is in a spike, each separate fructification being peltate and gaping at its many-valved base: Hedwig has determined the flowers of the Horsetail's and Adder's tongue to be hermaphrodite. Corn Horsetail has these spikes on a naked stem, and other leafy barren stems come up later in the season. Wood Horsetail has the leaves compound, or dia vided, and the spikes at the end of the fame stems. A species common in ditches has fearcely any leaves, and is perfectly fmooth: in which circumstance alone it differs from the Shave-grasso used in polishing, which is rough.

Ophioglossum alto, or Adder's-tongue, has Ophiogloffum. the fructifications on a spike, in a jointed row along each side of it; when they are

ripe, there joints gape transversely. Our

common species, which is found in moist meadows, may be known by the frond or

leaf being ovate.

O/munda likewise has a spike distinct from Osmunda the frond; it is branching, and each component fructification is globular. Moonwort, which grows on dry pastures, has one naked stem, and one pinnate frond, forming the whole of this little Fern. Flowering Fern, or Ofmund Royal, a large species found on bogs, has bipinnate fronds, bearing the fructifications in a raceme at top. Rough Spleenwort, has lanceolate, pinnatifid fronds, with the divisions confluent, quite entire and parallel: these are of two forts; the narrower being covered with fructifications on their backs, and the broader being barren. This therefore recedes from the character of the genus, in having a fertile frond instead of a spike, distinct from the barren one.

The remaining genera have the fructifica-Acrosticions invariably on the back of the fronds. In Acrostichum they cover the whole disk. In Pteris they are to be found only round Pteris.

the edge: the common Fern, or Brake', which is foabundant in uncultivated grounds and woods, has fuperdecompound, or triply-pinnate fronds, the leaflets pinnate, the lobes lance-shaped; the lowest pinnatisid,

and the upper ones lefs.

Afplenium.

As finded has the fructifications in lines, that are frequently parallel. Hart's-tongue has simple fronds, heart-tongued, that is, drawn out into length, and hollowed next the petiole: quite entire, and the petioles shaggy: this grows on rocks and in shady places. There are several smaller species with pinnate or decompound leaves, not uncommon on walls and rocks.

uncommon on wans and roo

Polypo-dium.

In Polypody the fructifications are in diftinct roundish dots, placed in rows, and increasing so much in size, as they advance to maturity, that they occupy the whole of the disk in some species, and great part of it in others. Common Polypody has pinnatished fronds, the pinnas or lobes oblong, a little toothed and obtuse; the root is scaly: this is common on trees, walls, and rocks. Many species that are generally called Ferns, from the disposition of the fructifications, are of this genus: of these, that which is most common has vulgarly

<sup>&</sup>lt;sup>t</sup> Pteris aquilina *Lin*. Blackw. t. 325. Ger. 1128.

<sup>a</sup> Afplenium Scolopendrium *Lin*. Curtis, Lond. I. 67. Ger. 1138.

v Polypodium vulgare Lin. Curtis, Lond. I. 68. Ger. 1132.

the name of *Male Fern*, and is found in woods, heaths, and on rocks, not covering the ground like the Brake, but in detached parcels: the fronds of this are doubly pinnate, the *pinnas* or lobes obtufe, and crenulate, or flightly notched, and the stem

chaffy.

Lastly, Adianthum has the fructifications Adianin terminal spots under the margin of the thum, frond, which is folded back. True Maidenhair\*, which is used, or supposed to be so, in the syrup of capillaire, is of this genus, and has decompound fronds, the component leaves alternate, and the lobes wedge-shaped, lobate, and pedicelled. It grows, but rarely, on rocks and walls. Schreber has separated the Equisetums or Horsetails, Lycopodium, Porella, Salvinia, Marsilea, Pilularia, and Isoetes, from the other orders, under the title of Miscellaneæ. For the true genera of serns, see Dr. Smith's Essay on Dorsiferous Ferns.

#### MOSSES,

The plants of the second order—the Mosses, have leaves like the more perfect vegetables, distinct from the stalk; and in this they differ from the ferns, in which the stalk and leaf always, and the fructification often, are blended, to form the frond.

Adianthum Capillus Veneris Lin. Jacq. mise. 2.

They

Polypodium Filix mas Lin. Blackw. t. 323. Vaill. t. 9. f. 2. Mor. Hist. s. 14. t. 3. f. 6. Ger. 1128.

They are perennial, and when ever so much dried up, will revive again with moisture; as Haller experienced in some specimens of Caspar Bauhin's Hortus Siccus, which must have lain in a dry state above a century. You know them by their air, or habit, as botanists usually call it. A general idea of their fructification has been already given, as far as it is visible to the naked eye; and we can only hope for a perfect account of it from a laborious examination with glasses of considerable magnifying powers.

The generic characters of the Mosses are taken from the heads, which are either sessible, or else the plant pushes them up on a slender naked stem; this Linnæus calls the Anther, but I shall beg leave rather to name it the Capsule\*: in sour genera\* it is naked, or not covered with a calyptre or veil; in the

other seven it is.

Lycopodium. ty Sphag- ca num. Ca

Lycopodium, or Wolf's-claw Moss, has a two valved, sessile capsule, without any calyptre. Sphagnum, or Bog-moss, has the capsule covered with a lid, and a smooth

y See Letter X.

<sup>a</sup> As Linnæus thinks it really is (See Genera, p. 556),

and Hedwig has shewn it to be.

b Lycopodium, Porella, Sphagnum & Phascum. Seperal of these are figured in English Botany.

omouth.

<sup>&</sup>lt;sup>2</sup> This has now been done by Hedwig in his Fundamentum Historiæ Naturalis Muscorum Frondosorum. Lipsiæ 1782, quarto; and Theoria generationis et fructificationis Plantarum Cryptogamicarum, Petrop. 1784, quarto; both with coloured plates of the parts of fructification much magnified.

mouth. The gray fpecies is common on bogs, covering vast tracts of them; and is known not only by its hoary appearance,

but by its deflected branches.

Polytrichum has a capsule covered with a Polytrichum. Iid, sitting on a small protuberant eminence, which is a kind of receptacle, and is called by Linnæus Apophysis, by Haller the Disk; the capsule is covered by a villous calyptre. There is a star or rose on a distinct individual, which has been generally taken for the pistilliserous flower; Haller rather thinks it is only a kind of bud, from which new branches spring. The common species, called Greater Golden Maidenhair, is known by its simple stem, and the parallelopiped form of the capsule. This is a large fort of Moss, and abundant in woods, heaths, and bogs.

The three remaining genera of Mosses, which are also the principal and most numerous, are thus distinguished. Mnium agrees with Polytrichum in having two sorts of fructification; the one a lidded capsule, covered with a smooth calyptre: the other a star or rose, in the disk of which are some globose little dusty bodies. Bryum and Hypnum have none of these stars, or roses: these have both a lidded capsule, covered with a smooth calyptre, and are

distinguished

c Sphagnum palustre Lin. Fl. Dan 474. Dillen. t. 32. f. 1.

d Polytrichum commune Lin. Dillen. t. 54. f. I. Ger. 1559.

diffinguished from each other by the stalk which supports the capsule being naked, and arising from a terminal tubercle in the first; whereas in the second it springs from the side of the branch, and is surrounded at bottom by a perichatium, scaly sheath, or receptacle.

Mnium.

One species of *Mnium*, whose filaments or capsular stalks are so sensible of moisture, that it has obtained the name of *bygrometric*, has no stems; it has nodding turbinate or pear-shaped capsules, reslex four-cornered calyptres, and ovate leaves forming a head; they are of a yellowish green, and the filaments are an inch and half high, and red or orange coloured.

Bryum.

One of the most common species of Bryum is the hairy, which covers the old thatch of cottages; this has the capsules rather erect, and the leaves ending in a hair, and recurved. Apple-form Bryum, has large spherical heads; and in the Pearform species, they are obovate, covered with an awl-shaped calyptre; the shoots are stemless, and the leaves are ovate and awnless. Brown Bryum has erect roundish

capsules,

<sup>&</sup>lt;sup>e</sup> Mnium hygrometricum *Lin*. Fl. Dan. 648. f. 2. Dillen. t. 52. f. 75. Mor. Hift. f. 15. t. 7. f. 17. Eng. Bot. 342.

Bryum truncatulum Lin. Curtis, Lond. II. 70. f. 2.

capsules, with a pointed lid. This is a very small Moss, growing close to the ground in thick tusts; the filaments are three or four lines high, and when the capsules have lost their lid, they have a truncated appearance, whence their name.

Silky Hypnumk, one of the most beauti-Hypnum ful, and not the least common of the genus, is known by its creeping shoots, its crowded erect branches, its awl-shaped leaves, and erect capsules. This grows both in dry places, fuch as on walls or trees; and in wet ones, as meadows: in the first, the leaves are narrow, and pressed close to the stalk; in the second, they are broader, spreading, and shining, like silk; the capfules are long, round, enlarging a little at bottom, with a flender ciliated mouth, a scarlet beaked lid, and a pale calyptre; they are supported by a purple stalk, or filament, from half an inch to an inch in height, furrounded at the base by a short thick scaly perichætium. This may ferve as a specimen of the numerous species of Hypnum; and we will now pass on to the third order of the Cryptogamia class. containing the

#### ALGÆ.

Alga or Flags, which are chiefly the Lichens or Liverworts, Sea-weeds, and

fome

h Hypnum fericeum Lin. Curtis, Lond. II. 69. Dillen. t. 42. f. 59. Mor. t. 5. f. 25. Many species of Hypnum and Bryum are figured in Engl. Bot.

fome few commonly called Mosses, but having in reality the character of this or-Marchan-der1. Of these last, common Marchantia" may ferve as an instance: it grows by Areams and fountains, in wet shady places, and on walls subject to a drip. There are two distinct fructifications in this genus. one standing out from the plant on a peduncle, and confisting of a peltated calyx or receptacle, covered with small one-petalled corollas underneath, each of which has one multifid anther or capfule; the other fessile. shaped like a cup or bell, and containing many little roundish bodies, which some take for feeds. The species here pointed out is distinguished by the common calyx being ten-cleft: it varies much in its appearance, and hence has its trivial name of many-form. This genus is evidently the connecting link between the Mosses, and the Lichens which we shall now examine.

Lichen.

The genus of Lichen has a roundifh, flattish, shining receptacle, or common calyx, seldom elevated; and a meal sprinkled over the leaves. The receptacle affording a variety of forms, has suggested a subdivision of this otherwise unwieldy genus, the leaf and manner of growth taking their parts in it. Lichens abundantly clothe the earth, rocks, and vegetables, especially trees;

<sup>1</sup> See Letter X.

m Marchantia polymorpha Lin. Dillen. t. 76. f. 6. Hedw. thcor. f. 123-133. Engl. Bot. 210.

STEELS CALABASE V.

fug as Lomnigary caned Modes, but in the form of meal, crust, leaf or thread: age, foil, and fituation, make fo great a second difference in their appearance, that numberlefs varieties have been advanced into species. The sections of the genus are, 1. The Tuberculate, confisting of a crust adhering closely to the bark of trees, or stones, above which roundish tubercles rise a little; these are rather irregular, a little flatted at top, and without any rink round them. Sometimes they run into regular figures, and refemble writing, or a map. 2. Scutellate, or such as have little shields, or roundish receptacles with a rim, and the disk somewhat depressed, arifing from a granulous crust more approaching to a leafy structure than in the former section, and not adhering so strongly. 2. Imbricate, composed of many small leaves. generally in an orbicular form, lying over each other, the least in the middle, and the largest on the outside; from some of these arise little shields, and others have little mealy tubercles at the ends of the leaves. Nothing is more common than a yellow species? of this section, on trees, walls, and rocks; the leaflets of it are curled, deep yellow above, and ash-coloured underneath; the shields are of a

<sup>&</sup>lt;sup>n</sup> Lichen scriptus Lin. Dillen. t. 18. f. 1.

<sup>°</sup> Lichen geographicus Lin. Dillen. t. 18. f. 5.

Engl. Bot. 245. Dillen. t. 24. f. 76, Engl. Bot. 194. Wall Liverwort.

lighter yellow, grow brown with age, and are thick fet towards the middle of the plant; other specimens, instead of shields, have a yellow meal spread over them: the leaves by age become greenish, and then of a brownish ash-colour, warted and leprous. 4. Leafy, properly fo called, confishing of one continued leafy substance, variously laciniate, cut or torn; these have generally large, wide shields, often on peduncles, either in the divisions of the leaves, or on their edges. Lungwort or Tree Lichen , which hangs from old oaks, and beeches in woods, has very large jagged leaves, fmooth, and ending obtufely; the upper furface is wrinkled and pitted, the lower downy: the shields are of the fize of a lentil, and placed on the edges of the leaves. 5. Coriaceous or Leathery: these are also leafy, but differ from those of the fourth section in consisting of several leaves, of a tougher texture, broader, less sharply laciniate, not branching, and generally adhering closer to the bodies on which they grow: the receptacles are very large, and from their resemblance to the round shields of the ancients, called pelta; they are generally on the edges of the leaves, and little or not at all notched on the edges. Ash-coloured Ground Liver-

Ger. 1566. Engl. Bot. 572.

wort' is of this fection: it is creeping, lobate, obtuse, and flat; veined underneath, and villous, with a rifing pelta or target on the edge: this species is very common on the ground in woods, and on heaths, particularly on old ant-hills: the leaves are ashcoloured, and white underneath. 6. Um-bilicate or hollowed like the navel, and footy, or appearing black, or as if burnt. 7. Cup-bearing, confifting of a granulous crust, in process of time unfolding into little leaves irregularly laciniate: from thefe arises a stipe or stem supporting hollow conical receptacles refembling little tea-cups or drinking-glasses, whose edge is often set with brown or scarlet tubercles. The different appearances of Cup-mo/s are probably but varieties arising from the different age of the plant. 8. Shrubby, or refembling shrubs or coral: these consist of a leafy crust like the last, but they have no cups, only tubercles, and they are branched. The famous Rhen-deer Moss' is of this

Lichen caninus Lin. Fl. Dan. 767. f. 2. Dillen. t. 27. f. 102. Mor. f. 15. t. 7. f. 1. This is the species formerly recommended against the bite of mad dogs, mixed with white pepper: but it is a remedy now exploded.

K k 2 fection:

Lichen rangiferinus Lin. Ft. Dan. 180. Dillen. t. 16. f. 29, 30. Engl. Bot t. 173. This elegant and accurate work is rich in figures of Lichens and other genera of Algae—Marchantia, Jungermania, and some others, are separated from the Algae by Schreber, under the name of Hepatica.

fection: it is perforate, very much branched, and the small branches are nodding: it grows on heaths and mountainous paf-tures with us. 9. Thready, or confifting of mere round, folid stiff stalks or threads, frequently covered or incrusted with a meal, which is very inflammable, and terminating in dry globules, a little hollowed, and without any rim. These most of them hang from the boughs of trees, and hence have the name of Treemoss. But this very numerous and widely diffused genus has already detained us too long.

The Sea-weeds are comprehended in three genera-Ulva or Laven, Fucus and Conserva. In the first, Ulva, the fructifications are in a diaphanous membrane, and the fubstance of the plant is membranaceous, at first bladdery, but afterwards leafy. Fu-

Fucus. cus, Wrack, or Sea-weed properly so called, has two kinds of bladders, the one smooth, hollow; and interwoven with hairs; the other smooth, filled with a jelly, in which are immersed small personated grains, in -each of which is supposed to be a feed: the texture of these plants is coriaceous or

Conservaleathery. Conserva are composed of unequal tubercles, in very long capillary fibres, which are either continued or jointed. The two last genera will furnish you with

abundant

t That is, there are little holes in the axils of the branches, as if made with a pin.

abundant amusement whenever you are led to spend a little time on the sea coast; but the species are so numerous, that the examination of the specific differences would carry me into too wide a field: we will pass on therefore to the last order of this last class of vegetable nature—the

### FUNGI OR MUSHROOMS,

which are univerfally known by their fingular structure and appearance; without branches, leaves, flowers, or any thing we can certainly call fructification, and scarcely any root. The Agaric, one of the princi-Agaricus, pal genera in this order, is known by its horizontal manner of growing, and by having lamellæ or gills underneath ". The Champignon v, or common eatable Mushroom, is one of these, and has the following characters—the head is convex, fealy, white; and supported on a stipe or stalk; the gills are red; that which has white gills is very like this, and though far inferior in quality, is not poisonous w. The Chanterelle , or little yellow Mushroom, so common in the fairy rings on dry pastures, is also stipitate, with the gills loose, branched

<sup>&</sup>quot; See plate 38 of this work.

and decurrent. What is commonly called Agaric in medicine, and is used in stopping of blood, is of another genus.

Boletus. Boletus which grows horizontally like the last, but instead of gills, has pores on the under surface.

Phallus. Morely is a fungus that is reticulate or netted all over the outfide or upper furface, and smooth beneath. The esculent species has the head egg shaped and cellular, the stipe or stem naked and wrinkled.

Lycoperdon. ifh fungus, filled with a mealy fubstance, taken for feed: this species is globular, folid, muricated, or rough on the outside, without any root, and growing wholly under ground: the other forts are full of dust, which they throw out when ripe, and are wholly above ground except their roots. Common Puff-ball<sup>2</sup> is roundish, and discharges its dust by a torn aperture in the top; this varies much in form, and also in size, from a little ball to that of a

man's head.

After all, the objects of this order are not univerfally allowed to be plants, but are fuspected, though seemingly without much

reason, to be formed by animals, for their habitation, after the manner of Zoophytes or corals. But this is a subject too difficult and nice for our discussion: and perhaps, after all, the fungi may prove to be one of those links in the chain of nature. which unite the vegetable to the animal kingdom; and though they should turn out to be the habitation of minute infects. and to be formed for and even by them, yet they certainly have the growth and texture of plants; and it is now well afcertained that they produce and are produced from feed, like other vegetables. Nature is full of these wonders, dear cousin; we are admitted to the view of a very small portion of it only; there is little hope then that we should be able to understand its relations fully, or to unravel all its mysteries.
